About Apache Cassandra

About this document

Welcome to the Cassandra documentation provided by DataStax. To ensure that you get the best experience in using this document, take a moment to look at the Tips for using DataStax documentation (page 1).

The landing pages (page 2) provide information about supported platforms, product compatibility, planning and testing cluster deployments, recommended production settings, troubleshooting, third-party software, resources for additional information, administrator and developer topics, and earlier documentation.

Overview of Apache Cassandra

Apache Cassandra™ is a massively scalable open source NoSQL database. Cassandra is perfect for managing large amounts of structured, semi-structured, and unstructured data across multiple datacenters and the cloud. Cassandra delivers continuous availability, linear scalability, and operational simplicity across many commodity servers with no single point of failure, along with a powerful dynamic data model designed for maximum flexibility and fast response times.

The latest version of Apache Cassandra 3.0 is 3.0.9.

How does Cassandra work?

Cassandra’s built-for-scale architecture means that it is capable of handling petabytes of information and thousands of concurrent users/operations per second.

<table>
<thead>
<tr>
<th>Cassandra is a partitioned row store database</th>
<th>Cassandra’s architecture allows any authorized user (page 117) to connect to any node in any datacenter and access data using the CQL language. For ease of use, CQL uses a similar syntax to SQL. The most basic way to interact with Cassandra is using the CQL shell, cqlsh (page 3). Using cqlsh, you can create keyspaces and tables, insert and query tables, plus much more. This Cassandra release works with CQL for Cassandra 2.2 and later (page 4). If you prefer a graphical tool, you can use DataStax DevCenter (page 5). For production, DataStax supplies a number drivers (page 6) so that CQL statements can be passed from client to cluster and back.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatic data distribution</td>
<td>Cassandra provides automatic data distribution across all nodes that participate in a ring or database cluster. There is nothing programmatic that a developer or administrator needs to do or code to distribute data across a cluster because data is transparently partitioned across all nodes in a cluster.</td>
</tr>
</tbody>
</table>

Apache Cassandra 3.0 for DSE 5.0 (Earlier version)
About Apache Cassandra

Cassandra also provides built-in and customizable replication, which stores redundant copies of data across nodes that participate in a Cassandra ring. This means that if any node in a cluster goes down, one or more copies of that node’s data is available on other machines in the cluster. Replication can be configured to work across one datacenter, many datacenters, and multiple cloud availability zones.

Cassandra supplies linear scalability, meaning that capacity may be easily added simply by adding new nodes online. For example, if 2 nodes can handle 100,000 transactions per second, 4 nodes will support 200,000 transactions/sec and 8 nodes will tackle 400,000 transactions/sec:

How is Cassandra different from relational databases?

Cassandra is designed from the ground up as a distributed database with peer-to-peer communication. As a best practice, queries should be one per table. Data is denormalized to make this possible. For this reason, the concept of JOINs between tables does not exist, although client-side joins can be used in applications.

What is NoSQL?

Most common translation is "Not only SQL", meaning a database that uses a method of storage different from a relational, or SQL, database. There are many different types of NoSQL databases, so a direct comparison of even the most used types is not useful. Database administrators today must be polyglot-friendly, meaning they must know how to work with many different RDBMS and NoSQL databases.

What is CQL?

Cassandra Query Language (CQL) is the primary interface into the Cassandra DBMS. Using CQL is similar to using SQL (Structured Query Language). CQL and SQL share the same abstract idea of a table constructed of columns and rows. The main difference from SQL is that Cassandra does not support joins or subqueries. Instead, Cassandra emphasizes
denormalization through CQL features like collections and clustering specified at the schema level.

CQL is the recommended way to interact with Cassandra. Performance and the simplicity of reading and using CQL is an advantage of modern Cassandra over older Cassandra APIs.

The CQL documentation (page ) contains a data modeling topic (page ), examples, and command reference.

How do I interact with Cassandra?

The most basic way to interact with Cassandra is using the CQL shell, cqlsh. Using cqlsh (page ), you can create keyspaces and tables, insert and query tables, plus much more. If you prefer a graphical tool, you can use DevCenter (page ). For production, DataStax supplies a number of drivers (page ) in various programming languages, so that CQL statements can be passed from client to cluster and back.

How can I move data to/from Cassandra?

Data is inserted using the CQL INSERT command, the CQL COPY command and CSV files, or sstableloader (page 388). But in reality, you need to consider how your client application will query the tables, and do data modeling first. The paradigm shift between relational and NoSQL means that a straight move of data from an RDBMS database to Cassandra will be doomed to failure.

What other tools come with Cassandra?

Cassandra automatically installs nodetool (page 250), a useful command-line management tool for Cassandra. A tool for load-stressing and basic benchmarking, cassandra-stress (page 372), is also installed by default.

What kind of hardware/cloud environment do I need to run Cassandra?

Cassandra is designed to run on commodity hardware (page ) with common specifications. In the cloud (page 80), Cassandra is adapted for most common offerings.

What's new in Apache Cassandra 3.0

Note: Cassandra is now releasing on a tick-to-ock schedule.

The latest version of Apache Cassandra 3.0 is 3.0.9.

The CHANGES.txt describes the changes in detail. You can view all version changes by branch or tag in the drop-down list on the changes page.

| **DataStax AMI does not install Cassandra 3.0 or 3.x**  | You can install Cassandra 2.1 and earlier versions on Amazon EC2 using the DataStax AMI (Amazon Machine Image) as described in the [AMI documentation](#) for Cassandra 2.1.  
To install Cassandra 3.0 and later on Amazon EC2, use a [trusted AMI](#) for your platform and the appropriate [install method](#) for that platform. |
Understanding the architecture

Architecture in brief

Cassandra is designed to handle big data workloads across multiple nodes with no single point of failure. Its architecture is based on the understanding that system and hardware failures can and do occur. Cassandra addresses the problem of failures by employing a peer-to-peer distributed system across homogeneous nodes where data is distributed among all nodes in the cluster. Each node frequently exchanges state information about itself and other nodes across the cluster using peer-to-peer gossip communication protocol. A sequentially written commit log on each node captures write activity to ensure data durability. Data is then indexed and written to an in-memory structure, called a memtable, which resembles a write-back cache. Each time the memory structure is full, the data is written to disk in an SSTables data file. All writes are automatically partitioned and replicated throughout the cluster. Cassandra periodically consolidates SSTables using a process called compaction, discarding obsolete data marked for deletion with a tombstone. To ensure all data across the cluster stays consistent, various repair mechanisms are employed.

Cassandra is a partitioned row store database, where rows are organized into tables with a required primary key. Cassandra's architecture allows any authorized user to connect to any node in any datacenter and access data using the CQL language. For ease of use, CQL uses a similar syntax to SQL and works with table data. Developers can access CQL through cqlsh, DevCenter, and via drivers for application languages. Typically, a cluster has one keyspace per application composed of many different tables.

Client read or write requests can be sent to any node in the cluster. When a client connects to a node with a request, that node serves as the coordinator for that particular client operation. The coordinator acts as a proxy between the client application and the nodes that own the data being requested. The coordinator determines which nodes in the ring should get the request based on how the cluster is configured.

Key structures

- Node
  Where you store your data. It is the basic infrastructure component of Cassandra.

- datacenter
  A collection of related nodes. A datacenter can be a physical datacenter or virtual datacenter. Different workloads should use separate datacenters, either physical or virtual. Replication is set by datacenter. Using separate datacenters prevents Cassandra transactions from being impacted by other workloads and keeps requests close to each other for lower latency. Depending on the replication factor, data can be written to multiple datacenters. Datacenters must never span physical locations.
Understanding the architecture

- **Cluster**
  A cluster contains one or more datacenters. It can span physical locations.

- **Commit log**
  All data is written first to the commit log for durability. After all its data has been flushed to SSTables, it can be archived, deleted, or recycled.

- **SSTable**
  A sorted string table (SSTable) is an immutable data file to which Cassandra writes memtables periodically. SSTables are append only and stored on disk sequentially and maintained for each Cassandra table.

- **CQL Table**
  A collection of ordered columns fetched by table row. A table consists of columns and has a primary key.

**Key components for configuring Cassandra**

- **Gossip (page 21)**
  A peer-to-peer communication protocol to discover and share location and state information about the other nodes in a Cassandra cluster. Gossip information is also persisted locally by each node to use immediately when a node restarts.

- **Partitioner (page 26)**
  A partitioner determines which node will receive the first replica of a piece of data, and how to distribute other replicas across other nodes in the cluster. Each row of data is uniquely identified by a primary key, which may be the same as its partition key, but which may also include other clustering columns. A partitioner is a hash function that derives a token from the primary key of a row. The partitioner uses the token value to determine which nodes in the cluster receive the replicas of that row. The Murmur3Partitioner (page 27) is the default partitioning strategy for new Cassandra clusters and the right choice for new clusters in almost all cases.

  You must set the partitioner and assign the node a num_tokens (page 100) value for each node. The number of tokens you assign depends on the hardware capabilities (page 100) of the system. If not using virtual nodes (vnodes), use the initial_token (page 100) setting instead.

- **Replication factor (page 25)**
  The total number of replicas across the cluster. A replication factor of 1 means that there is only one copy of each row on one node. A replication factor of 2 means two copies of each row, where each copy is on a different node. All replicas are equally important; there is no primary or master replica. You define the replication factor for each
Understanding the architecture

datacenter. Generally you should set the replication strategy greater than one, but no
more than the number of nodes in the cluster.

- **Replica placement strategy** *(page 25)*

  Cassandra stores copies (replicas) of data on multiple nodes to ensure reliability
  and fault tolerance. A replication strategy determines which nodes to place replicas
  on. The first replica of data is simply the first copy; it is not unique in any sense. The
  **NetworkTopologyStrategy** *(page 25)* is highly recommended for most deployments
  because it is much easier to expand to multiple datacenters when required by future
  expansion.

  When creating a keyspace, you must define the replica placement strategy and the
  number of replicas you want.

- **Snitch** *(page 28)*

  A snitch defines groups of machines into datacenters and racks (the topology) that the
  replication strategy uses to place replicas.

  You must configure a snitch *(page 28)* when you create a cluster. All snitches use
  a dynamic snitch layer, which monitors performance and chooses the best replica
  for reading. It is enabled by default and recommended for use in most deployments.
  Configure dynamic snitch thresholds for each node in the cassandra.yaml configuration
  file.

  The default **SimpleSnitch** *(page 29)* does not recognize datacenter or rack
  information. Use it for single-datacenter deployments or single-zone in public clouds. The
  **GossipingPropertyFileSnitch** *(page 31)* is recommended for production. It defines a
  node’s datacenter and rack and uses **gossip** *(page ) for propagating this information
  to other nodes.

- **The cassandra.yaml configuration file** *(page 86)*

  The main configuration file for setting the initialization properties for a cluster, caching
  parameters for tables, properties for tuning and resource utilization, timeout settings,
  client connections, backups, and security.

  By default, a node is configured to store the data it manages in a directory set in the
  cassandra.yaml file.

  The location of the cassandra.yaml *(page* file depends on the type of installation:

  | DataStax Enterprise 5.0 Installer-Services and package installations | /etc/dse/cassandra/cassandra.yaml |
  | DataStax Enterprise 5.0 Installer-No Services and tarball installations | install_location/resources/cassandra/ conf/cassandra.yaml |
  | Cassandra package installations | /etc/cassandra/cassandra.yaml |
  | Cassandra tarball installations | install_location/resources/cassandra/ conf/cassandra.yaml |
In a production cluster deployment, you can change the `commitlog-directory` (page 88) to a different disk drive from the `data_file_directories` (page 88).

- **System keyspace table properties** (page )

  You set storage configuration attributes on a per-keyspace or per-table basis programmatically or using a client application, such as CQL.

**Related information:**

- **The cassandra.yaml configuration file** [The cassandra.yaml file is the main configuration file for Cassandra.] (page 86)
- **Install locations** [Install location topics.] (page 85)

**Internode communications (gossip)**

Gossip is a peer-to-peer communication protocol in which nodes periodically exchange state information about themselves and about other nodes they know about. The gossip process runs every second and exchanges state messages with up to three other nodes in the cluster. The nodes exchange information about themselves and about the other nodes that they have gossiped about, so all nodes quickly learn about all other nodes in the cluster. A gossip message has a version associated with it, so that during a gossip exchange, older information is overwritten with the most current state for a particular node.

To prevent problems in gossip communications, use the same list of seed nodes for all nodes in a cluster. This is most critical the first time a node starts up. By default, a node remembers other nodes it has gossiped with between subsequent restarts. The seed node designation has no purpose other than bootstrapping the gossip process for new nodes joining the cluster. Seed nodes are not a single point of failure, nor do they have any other special purpose in cluster operations beyond the bootstrapping of nodes.

**Attention:** In multiple data-center clusters, include at least one node from each datacenter (replication group) in the seed list. Designating more than a single seed node per datacenter is recommended for fault tolerance. Otherwise, gossip has to communicate with another datacenter when bootstrapping a node.

Making every node a seed node is not recommended because of increased maintenance and reduced gossip performance. Gossip optimization is not critical, but it is recommended to use a small seed list (approximately three nodes per datacenter).

**Failure detection and recovery**

Failure detection is a method for locally determining from gossip state and history if another node in the system is down or has come back up. Cassandra uses this information to avoid routing client requests to unreachable nodes whenever possible. (Cassandra can also avoid routing requests to nodes that are alive, but performing poorly, through the dynamic snitch (page 28).)
Understanding the architecture

The gossip process tracks state from other nodes both directly (nodes gossiping directly to it) and indirectly (nodes communicated about secondhand, third-hand, and so on). Rather than have a fixed threshold for marking failing nodes, Cassandra uses an accrual detection mechanism to calculate a per-node threshold that takes into account network performance, workload, and historical conditions. During gossip exchanges, every node maintains a sliding window of inter-arrival times of gossip messages from other nodes in the cluster. Configuring the `phi_convict_threshold` (page 95) property adjusts the sensitivity of the failure detector. Lower values increase the likelihood that an unresponsive node will be marked as down. Use the default value for most situations, but increase it to 10 or 12 for Amazon EC2 (due to frequently encountered network congestion). In unstable network environments (such as EC2 at times), raising the value to 10 or 12 helps prevent false failures. Values higher than 12 and lower than 5 are not recommended.

Node failures can result from various causes such as hardware failures and network outages. Node outages are often transient but can last for extended periods. Because a node outage rarely signifies a permanent departure from the cluster it does not automatically result in permanent removal of the node from the ring. Other nodes will periodically try to re-establish contact with failed nodes to see if they are back up. To permanently change a node’s membership in a cluster, administrators must explicitly add or remove nodes from a Cassandra cluster using the `nodetool utility` (page 250).

When a node comes back online after an outage, it may have missed writes for the replica data it maintains. Repair mechanisms (page 212) exist to recover missed data, such as hinted handoffs and manual repair with `nodetool repair` (page 311). The length of the outage will determine which repair mechanism is used to make the data consistent.

**Data distribution and replication**

In Cassandra, data distribution and replication go together. Data is organized by table and identified by a primary key, which determines which node the data is stored on. Replicas are copies of rows. When data is first written, it is also referred to as a replica.

Factors influencing replication include:

- **Virtual nodes** (page 23): assigns data ownership to physical machines.
- **Partitioner** (page 26): partitions the data across the cluster.
- **Replication strategy** (page 25): determines the replicas for each row of data.
- **Snitch** (page 28): defines the topology information that the replication strategy uses to place replicas.

**Consistent hashing**

Consistent hashing allows distribution of data across a cluster to minimize reorganization when nodes are added or removed. Consistent hashing partitions data based on the partition key. (For an explanation of partition keys and primary keys, see the Data modeling example (page ) in CQL for Cassandra 2.2 and later.)

For example, if you have the following data:

- ...
Cassandra assigns a hash value to each partition key:

Each node in the cluster is responsible for a range of data based on the hash value.

Figure 1: Hash values in a four node cluster

Cassandra places the data on each node according to the value of the partition key and the range that the node is responsible for. For example, in a four node cluster, the data in this example is distributed as follows:

**Virtual nodes**

Virtual nodes, known as Vnodes, distribute data across nodes at a finer granularity than can be easily achieved if calculated tokens are used. Vnodes simplify many tasks in Cassandra:

- Tokens are automatically calculated and assigned to each node.
- Rebalancing a cluster is automatically accomplished when adding or removing nodes. When a node joins the cluster, it assumes responsibility for an even portion of data from the other nodes in the cluster. If a node fails, the load is spread evenly across other nodes in the cluster.
- Rebuilding a dead node is faster because it involves every other node in the cluster.
- The proportion of vnodes assigned to each machine in a cluster can be assigned, so smaller and larger computers can be used in building a cluster.
For more information, see the article Virtual nodes in Cassandra 1.2. To convert an existing cluster to vnodes, see Enabling virtual nodes on an existing production cluster (page 155).

**How data is distributed across a cluster (using virtual nodes)**

Prior to Cassandra 1.2, you had to calculate and assign a single token (page ) to each node in a cluster. Each token determined the node’s position in the ring and its portion of data according to its hash value. In Cassandra 1.2 and later, each node is allowed many tokens. The new paradigm is called virtual nodes (vnodes). Vnodes allow each node to own a large number of small partition ranges (page ) distributed throughout the cluster. Vnodes also use consistent hashing to distribute data but using them doesn’t require token generation and assignment.

Figure 2: Virtual vs single-token architecture
The top portion of the graphic shows a cluster without vnodes. In this paradigm, each node is assigned a single token that represents a location in the ring. Each node stores data determined by mapping the partition key (page 20) to a token value within a range from the previous node to its assigned value. Each node also contains copies of each row from other nodes in the cluster. For example, if the replication factor is 3, range E replicates to nodes 5, 6, and 1. Notice that a node owns exactly one contiguous partition range in the ring space.

The bottom portion of the graphic shows a ring with vnodes. Within a cluster, virtual nodes are randomly selected and non-contiguous. The placement of a row is determined by the hash of the partition key within many smaller partition ranges belonging to each node.

**Data replication**

Cassandra stores replicas on multiple nodes to ensure reliability and fault tolerance. A replication strategy determines the nodes where replicas are placed. The total number of replicas across the cluster is referred to as the replication factor. A replication factor of 1 means that there is only one copy of each row in the cluster. If the node containing the row goes down, the row cannot be retrieved. A replication factor of 2 means two copies of each row, where each copy is on a different node. All replicas are equally important; there is no primary or master replica. As a general rule, the replication factor should not exceed the number of nodes in the cluster. However, you can increase the replication factor and then add the desired number of nodes later.

Two replication strategies are available:

- **SimpleStrategy**: Use only for a single datacenter (page 20) and one rack. If you ever intend more than one datacenter, use the NetworkTopologyStrategy.
- **NetworkTopologyStrategy**: Highly recommended for most deployments because it is much easier to expand to multiple datacenters when required by future expansion.

**SimpleStrategy**

Use only for a single datacenter and one rack. SimpleStrategy places the first replica on a node determined by the partitioner. Additional replicas are placed on the next nodes clockwise in the ring without considering topology (rack or datacenter location).

**NetworkTopologyStrategy**

Use NetworkTopologyStrategy when you have (or plan to have) your cluster deployed across multiple datacenters. This strategy specifies how many replicas you want in each datacenter.

NetworkTopologyStrategy places replicas in the same datacenter by walking the ring clockwise until reaching the first node in another rack. NetworkTopologyStrategy attempts to place replicas on distinct racks because nodes in the same rack (or similar physical grouping) often fail at the same time due to power, cooling, or network issues.

When deciding how many replicas to configure in each datacenter, the two primary considerations are (1) being able to satisfy reads locally, without incurring cross
Understanding the architecture

data-center latency, and (2) failure scenarios. The two most common ways to configure multiple datacenter clusters are:

- Two replicas in each datacenter: This configuration tolerates the failure of a single node per replication group and still allows local reads at a consistency level of **ONE**.
- Three replicas in each datacenter: This configuration tolerates either the failure of one node per replication group at a strong consistency level of **LOCAL_QUORUM** or multiple node failures per datacenter using consistency level **ONE**.

Asymmetrical replication groupings are also possible. For example, you can have three replicas in one datacenter to serve real-time application requests and use a single replica elsewhere for running analytics.

Replication strategy is defined per keyspace, and is set during keyspace creation. To set up a keyspace, see **creating a keyspace (page 314)**.

For more about replication strategy options, see **Changing keyspace replication strategy (page 195)**.

**Partitioners**

A partitioner determines how data is distributed across the nodes in the cluster (including replicas). Basically, a partitioner is a function for deriving a token representing a row from its partition key, typically by hashing. Each row of data is then distributed across the cluster by the value of the token.

Both the **Murmur3Partitioner** and **RandomPartitioner** use tokens to help assign equal portions of data to each node and evenly distribute data from all the tables throughout the ring or other grouping, such as a keyspace. This is true even if the tables use different partition keys (page 156), such as usernames or timestamps. Moreover, the read and write requests to the cluster are also evenly distributed and load balancing is simplified because each part of the hash range receives an equal number of rows on average. For more detailed information, see **Consistent hashing (page 22)**.

The main difference between the two partitioners is how each generates the token hash values. The **RandomPartitioner** uses a cryptographic hash that takes longer to generate than the **Murmur3Partitioner**. Cassandra doesn’t really need a cryptographic hash, so using the **Murmur3Partitioner** results in a 3-5 times improvement in performance.

Cassandra offers the following partitioners that can be set in the **cassandra.yaml file (page 86)**.

- **Murmur3Partitioner** (default): uniformly distributes data across the cluster based on MurmurHash hash values.
- **RandomPartitioner**: uniformly distributes data across the cluster based on MD5 hash values.
- **ByteOrderedPartitioner**: keeps an ordered distribution of data lexically by key bytes.
The Murmur3Partitioner is the default partitioning strategy for Cassandra 1.2 and later new clusters and the right choice for new clusters in almost all cases. However, the partitioners are not compatible and data partitioned with one partitioner cannot be easily converted to the other partitioner.

Note: If using virtual nodes (vnodes), you do not need to calculate the tokens. If not using vnodes, you must calculate the tokens to assign to the initial_token (page 100) parameter in the cassandra.yaml file. See Generating tokens (page 164) and use the method for the type of partitioner you are using.

The location of the cassandra.yaml (page) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>cassandra.yaml Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>installations</td>
<td></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/ conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/ conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

Related information:
Install locations [Install location topics.] (page 85)

Murmur3Partitioner

The Murmur3Partitioner is the default partitioner. The Murmur3Partitioner provides faster hashing and improved performance than the RandomPartitioner. The Murmur3Partitioner can be used with vnodes. However, if you don't use vnodes, you must calculate the tokens, as described in Generating tokens (page 164).

Use Murmur3Partitioner for new clusters; you cannot change the partitioner in existing clusters that use a different partitioner. The Murmur3Partitioner uses the MurmurHash function. This hashing function creates a 64-bit hash value of the partition key. The possible range of hash values is from \(-2^{63}\) to \(+2^{63}-1\).

When using the Murmur3Partitioner, you can page through all rows using the token function (page ) in a CQL query.

RandomPartitioner

The RandomPartitioner was the default partitioner prior to Cassandra 1.2. It is included for backwards compatibility. The RandomPartitioner can be used with virtual nodes (vnodes). However, if you don't use vnodes, you must calculate the tokens, as described in Generating tokens (page 164). The RandomPartitioner distributes data evenly across the nodes using an MD5 hash value of the row key. The possible range of hash values is from 0 to \(2^{127}-1\).
When using the `RandomPartitioner`, you can page through all rows using the `token` function (page) in a CQL query.

**ByteOrderedPartitioner**

Cassandra provides the `ByteOrderedPartitioner` for ordered partitioning. It is included for backwards compatibility. This partitioner orders rows lexically by key bytes. You calculate tokens by looking at the actual values of your partition key data and using a hexadecimal representation of the leading character(s) in a key. For example, if you wanted to partition rows alphabetically, you could assign an A token using its hexadecimal representation of 41.

Using the ordered partitioner allows ordered scans by primary key. This means you can scan rows as though you were moving a cursor through a traditional index. For example, if your application has user names as the partition key, you can scan rows for users whose names fall between Jake and Joe. This type of query is not possible using randomly partitioned partition keys because the keys are stored in the order of their MD5 hash (not sequentially).

Although having the capability to do range scans on rows sounds like a desirable feature of ordered partitioners, there are ways to achieve the same functionality using table indexes (page).

Using an ordered partitioner is not recommended for the following reasons:

**Difficult load balancing**

More administrative overhead is required to load balance the cluster. An ordered partitioner requires administrators to manually calculate partition ranges (page) based on their estimates of the partition key distribution. In practice, this requires actively moving node tokens around to accommodate the actual distribution of data once it is loaded.

**Sequential writes can cause hot spots**

If your application tends to write or update a sequential block of rows at a time, then the writes are not be distributed across the cluster; they all go to one node. This is frequently a problem for applications dealing with timestamped data.

**Uneven load balancing for multiple tables**

If your application has multiple tables, chances are that those tables have different row keys and different distributions of data. An ordered partitioner that is balanced for one table may cause hot spots and uneven distribution for another table in the same cluster.

**Snitches**

A snitch determines which datacenters and racks nodes belong to. They inform Cassandra about the network topology so that requests are routed efficiently and allows Cassandra to distribute replicas by grouping machines into datacenters and racks. Specifically, the replication strategy places the replicas based on the information provided by the new snitch. All nodes must return to the same rack and datacenter. Cassandra does its best not to have more than one replica on the same rack (which is not necessarily a physical location).
**Dynamic snitching**

By default, all snitches also use a dynamic snitch layer that monitors read latency and, when possible, routes requests away from poorly-performing nodes. The dynamic snitch is enabled by default and is recommended for use in most deployments. For information on how this works, see Dynamic snitching in Cassandra: past, present, and future. Configure dynamic snitch thresholds for each node in the cassandra.yaml configuration file.

For more information, see the properties listed under Failure detection and recovery (page 21).

The location of the cassandra.yaml file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

**SimpleSnitch**

The SimpleSnitch (default) is used only for single-datacenter deployments. It does not recognize datacenter or rack information and can be used only for single-datacenter deployments or single-zone in public clouds. It treats strategy order as proximity, which can improve cache locality when disabling read repair.

Using a SimpleSnitch, you define the keyspace (page ) to use SimpleStrategy and specify a replication factor.

**RackInferringSnitch**

The RackInferringSnitch determines the proximity of nodes by rack and datacenter, which are assumed to correspond to the 3rd and 2nd octet of the node’s IP address, respectively. This snitch is best used as an example for writing a custom snitch class (unless this happens to match your deployment conventions).
Understanding the architecture

PropertyFileSnitch

This snitch determines proximity as determined by rack and datacenter. It uses the network details located in the cassandra-topology.properties file. When using this snitch, you can define your datacenter names to be whatever you want. Make sure that the datacenter names correlate to the name of your datacenters in the keyspace definition (page 24). Every node in the cluster should be described in the cassandra-topology.properties file, and this file should be exactly the same on every node in the cluster.

The location of the cassandra-topology.properties file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-topology.properties</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-topology.properties</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-topology.properties</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-topology.properties</td>
</tr>
</tbody>
</table>

1. If you had non-uniform IPs and two physical datacenters with two racks in each, and a third logical datacenter for replicating analytics data, the cassandra-topology.properties file might look like this:

   Note: datacenter and rack names are case-sensitive.

```
# datacenter One
175.56.12.105=DC1:RAC1
175.50.13.200=DC1:RAC1
175.54.35.197=DC1:RAC1
120.53.24.101=DC1:RAC2
120.55.16.200=DC1:RAC2
120.57.102.103=DC1:RAC2

# datacenter Two
110.56.12.120=DC2:RAC1
110.50.13.201=DC2:RAC1
```
110.54.35.184=DC2:RAC1
50.33.23.120=DC2:RAC2
50.45.14.220=DC2:RAC2
50.17.10.203=DC2:RAC2

# Analytics Replication Group
172.106.12.120=DC3:RAC1
172.106.12.121=DC3:RAC1
172.106.12.122=DC3:RAC1

# default for unknown nodes
default =DC3:RAC1

## GossipingPropertyFileSnitch

This snitch is recommended for production. It uses rack and datacenter information for the local node defined in the cassandra-rackdc.properties file and propagates this information to other nodes via gossip.

The configuration for the GossipingPropertyFileSnitch is contained in the cassandra-rackdc.properties file.

The location of the cassandra-rackdc.properties file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra-rackdc.properties</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra-rackdc.properties</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra-rackdc.properties</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/conf/cassandra-rackdc.properties</code></td>
</tr>
</tbody>
</table>

To configure a node to use GossipingPropertyFileSnitch, edit the cassandra-rackdc.properties file as follows:

- Define the datacenter and Rack that include this node. The default settings:

  ```
  dc=DC1
  rack=RAC1
  ```

  **Note:** datacenter and rack names are case-sensitive.
• To save bandwidth, add the `prefer_local=true` option. This option tells Cassandra to use the local IP address when communication is not across different datacenters.

**Migrating from the PropertyFileSnitch to the GossipingPropertyFileSnitch**

To allow migration from the PropertyFileSnitch, the GossipingPropertyFileSnitch uses the `cassandra-topology.properties` file when present. Delete the file after the migration is complete. For more information about migration, see [Switching snitches](page 192).

**Note:** The GossipingPropertyFileSnitch always loads `cassandra-topology.properties` when that file is present. Remove the file from each node on any new cluster or any cluster migrated from the PropertyFileSnitch.

**Ec2Snitch**

Use the Ec2Snitch for simple cluster deployments on Amazon EC2 where all nodes in the cluster are within a single region.

In EC2 deployments, the region name is treated as the datacenter name and availability zones are treated as racks within a datacenter. For example, if a node is in the **us-east-1** region, **us-east** is the datacenter name and **1** is the rack location. (Racks are important for distributing replicas, but not for datacenter naming.) Because private IPs are used, this snitch does not work across multiple regions.

If you are using only a single datacenter, you do not need to specify any properties.

If you need multiple datacenters, set the `dc_suffix` options in the `cassandra-rackdc.properties` file. Any other lines are ignored.

For example, for each node within the **us-east** region, specify the datacenter in its `cassandra-rackdc.properties` file:

**Note:** datacenter names are case-sensitive.

• node0
  
  `dc_suffix=_1_cassandra`

• node1
  
  `dc_suffix=_1_cassandra`

• node2
  
  `dc_suffix=_1_cassandra`

• node3
  
  `dc_suffix=_1_cassandra`

• node4
Understanding the architecture

- node5

This results in three datacenters for the region:

<table>
<thead>
<tr>
<th>Datacenter Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east_1_cassandra</td>
</tr>
<tr>
<td>us-east_1_analytics</td>
</tr>
<tr>
<td>us-east_1_search</td>
</tr>
</tbody>
</table>

Note: The datacenter naming convention in this example is based on the workload. You can use other conventions, such as DC1, DC2 or 100, 200.

Keyspace strategy options

When defining your keyspace strategy options (page 87), use the EC2 region name, such as ``us-east``, as your datacenter name.

The location of the cassandra-rackdc.properties file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-rackdc.properties</td>
</tr>
</tbody>
</table>

**Ec2MultiRegionSnitch**

Use the Ec2MultiRegionSnitch for deployments on Amazon EC2 where the cluster spans multiple regions.

You must configure settings in both the cassandra.yaml file and the property file (cassandra-rackdc.properties) used by the Ec2MultiRegionSnitch.

Configuring cassandra.yaml for cross-region communication

The Ec2MultiRegionSnitch uses public IP designated in the broadcast_address to allow cross-region connectivity. Configure each node as follows:

1. In the cassandra.yaml, set the listen_address (page 87) to the private IP address of the node, and the broadcast_address (page 100) to the public IP address of the node.
Understanding the architecture

This allows Cassandra nodes in one EC2 region to bind to nodes in another region, thus enabling multiple datacenter support. For intra-region traffic, Cassandra switches to the private IP after establishing a connection.

2. Set the addresses of the seed nodes in the cassandra.yaml file to that of the public IP. Private IP are not routable between networks. For example:

```
seeds: 50.34.16.33, 60.247.70.52
```

To find the public IP address, from each of the seed nodes in EC2:

```
$ curl http://instance-data/latest/meta-data/public-ipv4
```

**Note:** Do not make all nodes seeds, see Internode communications (gossip) (page 21).

3. Be sure that the storage_port (page 102) or ssl_storage_port (page 116) is open on the public IP firewall.

Configuring the snitch for cross-region communication

In EC2 deployments, the region name is treated as the datacenter name and availability zones are treated as racks within a datacenter. For example, if a node is in the us-east-1 region, us-east is the datacenter name and 1 is the rack location. (Racks are important for distributing replicas, but not for datacenter naming.)

For each node, specify its datacenter in the cassandra-rackdc.properties. The `dc_suffix` option defines the datacenters used by the snitch. Any other lines are ignored.

In the example below, there are two cassandra datacenters and each datacenter is named for its workload. The datacenter naming convention in this example is based on the workload. You can use other conventions, such as DC1, DC2 or 100, 200. (datacenter names are case-sensitive.)
Understanding the architecture

<table>
<thead>
<tr>
<th>Region: us-east</th>
<th>Region: us-west</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node and datacenter:</td>
<td>Node and datacenter:</td>
</tr>
<tr>
<td>• node0</td>
<td>• node0</td>
</tr>
<tr>
<td>dc_suffix=_1_cassandra</td>
<td>dc_suffix=_1_cassandra</td>
</tr>
<tr>
<td>• node1</td>
<td>• node1</td>
</tr>
<tr>
<td>dc_suffix=_1_cassandra</td>
<td>dc_suffix=_1_cassandra</td>
</tr>
<tr>
<td>• node2</td>
<td>• node2</td>
</tr>
<tr>
<td>dc_suffix=_2_cassandra</td>
<td>dc_suffix=_2_cassandra</td>
</tr>
<tr>
<td>• node3</td>
<td>• node3</td>
</tr>
<tr>
<td>dc_suffix=_2_cassandra</td>
<td>dc_suffix=_2_cassandra</td>
</tr>
<tr>
<td>• node4</td>
<td>• node4</td>
</tr>
<tr>
<td>dc_suffix=_1_analytics</td>
<td>dc_suffix=_1_analytics</td>
</tr>
<tr>
<td>• node5</td>
<td>• node5</td>
</tr>
<tr>
<td>dc_suffix=_1_search</td>
<td>dc_suffix=_1_search</td>
</tr>
</tbody>
</table>

This results in four **us-east** datacenters:
- us-east_1_cassandra
- us-east_2_cassandra
- us-east_1_analytics
- us-east_1_search

This results in four **us-west** datacenters:
- us-west_1_cassandra
- us-west_2_cassandra
- us-west_1_analytics
- us-west_1_search

**Keyspace strategy options**

When defining your keyspace strategy options *(page)*, use the EC2 region name, such as `us-east`, as your datacenter name.

The location of the `cassandra-rackdc.properties` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra-rackdc.properties</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra-rackdc.properties</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra-rackdc.properties</code></td>
</tr>
<tr>

Install locations [Install location topics.] (page 85)

GoogleCloudSnitch

Use the GoogleCloudSnitch for Cassandra deployments on Google Cloud Platform across one or more regions. The region is treated as a datacenter and the availability zones are treated as racks within the datacenter. All communication occurs over private IP addresses within the same logical network.

The region name is treated as the datacenter name and zones are treated as racks within a datacenter. For example, if a node is in the `us-central1-a` region, `us-central1` is the datacenter name and `a` is the rack location. (Racks are important for distributing replicas, but not for datacenter naming.) This snitch can work across multiple regions without additional configuration.

If you are using only a single datacenter, you do not need to specify any properties.

If you need multiple datacenters, set the `dc_suffix` options in the `cassandra-rackdc.properties` file. Any other lines are ignored.

For example, for each node within the `us-central1` region, specify the datacenter in its `cassandra-rackdc.properties` file:

   Note: datacenter names are case-sensitive.

- **node0**
  `dc_suffix=_a_cassandra`

- **node1**
  `dc_suffix=_a_cassandra`

- **node2**
  `dc_suffix=_a_cassandra`

- **node3**
  `dc_suffix=_a_cassandra`

- **node4**
  `dc_suffix=_a_cassandra`
dc_suffix=_a_analytics

- node5
dc_suffix=_a_search

The location of the `cassandra-rackdc.properties` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>File Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra-rackdc.properties</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra-rackdc.properties</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra-rackdc.properties</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/conf/cassandra-rackdc.properties</code></td>
</tr>
</tbody>
</table>

**Note:** Datacenter and rack names are case-sensitive.

**CloudstackSnitch**

Use the CloudstackSnitch for Apache Cloudstack environments. Because zone naming is free-form in Apache Cloudstack, this snitch uses the widely-used `<country> <location> <az>` notation.
Database internals

Storage engine

Cassandra uses a storage structure similar to a Log-Structured Merge Tree, unlike a typical relational database that uses a B-Tree. Cassandra avoids reading before writing. Read-before-write, especially in a large distributed system, can result in large latencies in read performance and other problems. For example, two clients read at the same time; one overwrites the row to make update A, and the other overwrites the row to make update B, removing update A. This race condition will result in ambiguous query results - which update is correct?

To avoid using read-before-write for most writes in Cassandra, the storage engine groups inserts and updates in memory, and at intervals, sequentially writes the data to disk in append mode. Once written to disk, the data is immutable and is never overwritten. Reading data involves combining this immutable sequentially-written data to discover the correct query results. You can use Lightweight transactions (LWT) (page 59) to check the state of the data before writing. However, this feature is recommended only for limited use.

A log-structured engine that avoids overwrites and uses sequential I/O to update data is essential for writing to solid-state disks (SSD) and hard disks (HDD). On HDD, writing randomly involves a higher number of seek operations than sequential writing. The seek penalty incurred can be substantial. Because Cassandra sequentially writes immutable files, thereby avoiding write amplification and disk failure, the database accommodates inexpensive, consumer SSDs extremely well. For many other databases, write amplification is a problem on SSDs.

How Cassandra reads and writes data

To manage and access data in Cassandra, it is important to understand how Cassandra stores data. The hinted handoff feature plus Cassandra conformance and non-conformance to the ACID (atomic, consistent, isolated, durable) database properties are key concepts to understand reads and writes. In Cassandra, consistency refers to how up-to-date and synchronized a row of data is on all of its replicas.

Client utilities and application programming interfaces (APIs) for developing applications for data storage and retrieval are available (page 324).

How is data written?

Cassandra processes data at several stages on the write path, starting with the immediate logging of a write and ending in with a write of data to disk:

- Logging data in the commit log
- Writing data to the memtable
- Flushing data from the memtable
• Storing data on disk in SSTables

Logging writes and memtable storage

When a write occurs, Cassandra stores the data in a memory structure called memtable, and to provide configurable durability (page 86), it also appends writes to the commit log on disk. The commit log receives every write made to a Cassandra node, and these durable writes survive permanently even if power fails on a node. The memtable is a write-back cache of data partitions that Cassandra looks up by key. The memtable stores writes in sorted order until reaching a configurable limit, and then is flushed.

Flushing data from the memtable

To flush the data, Cassandra writes the data to disk, in the memtable-sorted order. A partition index is also created on the disk that maps the tokens to a location on disk. When the memtable content exceeds the configurable threshold (page 241) or the commitlog space exceeds the commitlog_total_space_in_mb, the memtable is put in a queue that is flushed to disk. The queue can be configured with the memtable_heap_space_in_mb or memtable_offheap_space_in_mb setting in the cassandra.yaml file. If the data to be flushed exceeds the memtable_cleanup_threshold, Cassandra blocks writes until the next flush succeeds. You can manually flush a table using nodetool flush (page 279) or nodetool drain (page 272) (flushes memtables without listening for connections to other nodes). To reduce the commit log replay time, the recommended best practice is to flush the memtable before you restart the nodes. If a node stops working, replaying the commit log restores to the memtable the writes that were there before it stopped.

Data in the commit log is purged after its corresponding data in the memtable is flushed to an SSTable on disk.

Storing data on disk in SSTables

Memtables and SSTables are maintained per table. The commit log is shared among tables. SSTables are immutable, not written to again after the memtable is flushed. Consequently, a partition is typically stored across multiple SSTable files. A number of other SSTable structures exist to assist read operations:

For each SSTable, Cassandra creates these structures:

Data (Data.db)
  The SSTable data
Primary Index (Index.db)
Bloom filter (page Filter.db)
A structure stored in memory that checks if row data exists in the memtable before accessing SSTables on disk

Compression Information (CompressionInfo.db)
A file holding information about uncompressed data length, chunk offsets and other compression information

Statistics (Statistics.db)
Statistical metadata about the content of the SSTable

Digest (Digest.crc32, Digest.adler32, Digest.sha1)
A file holding adler32 checksum of the data file

CRC (CRC.db)
A file holding the CRC32 for chunks in an uncompressed file.

SSTable Index Summary (SUMMARY.db)
A sample of the partition index stored in memory

SSTable Table of Contents (TOC.txt)
A file that stores the list of all components for the SSTable TOC

Secondary Index (SI_.*+.db)
Built-in secondary index. Multiple SIs may exist per SSTable

The SSTables are files stored on disk. The naming convention for SSTable files has changed with Cassandra 2.2 and later to shorten the file path. The data files are stored in a data directory that varies with installation. For each keyspace, a directory within the data directory stores each table. For example, /data/data/ks1/cf1-5be396077b811e3a3ab9dc4b9ac088d/la-1-big-Data.db represents a data file. ks1 represents the keyspace name to distinguish the keyspace for streaming or bulk loading data. A hexadecimal string, 5be396077b811e3a3ab9dc4b9ac088d in this example, is appended to table names to represent unique table IDs.

Cassandra creates a subdirectory for each table, which allows you to symlink a table to a chosen physical drive or data volume. This provides the capability to move very active tables to faster media, such as SSDs for better performance, and also divides tables across all attached storage devices for better I/O balance at the storage layer.

How is data maintained?

The Cassandra write process stores data in files called SSTables. SSTables are immutable. Instead of overwriting existing rows with inserts or updates, Cassandra writes new timestamped versions of the inserted or updated data in new SSTables. Cassandra does not perform deletes by removing the deleted data: instead, Cassandra marks it with tombstones (page ).

Over time, Cassandra may write many versions of a row in different SSTables. Each version may have a unique set of columns stored with a different timestamp. As SSTables accumulate, the distribution of data can require accessing more and more SSTables to retrieve a complete row.

To keep the database healthy, Cassandra periodically merges SSTables and discards old data. This process is called compaction.
Compaction

Compaction works on a collection of SSTables. From these SSTables, compaction collects all versions of each unique row and assembles one complete row, using the most up-to-date version (by timestamp) of each of the row’s columns. The merge process is performant, because rows are sorted by partition key (page) within each SSTable, and the merge process does not use random I/O. The new versions of each row is written to a new SSTable. The old versions, along with any rows that are ready for deletion, are left in the old SSTables, and are deleted as soon as pending reads are completed.

Compaction causes a temporary spike in disk space usage and disk I/O while old and new SSTables co-exist. As it completes, compaction frees up disk space occupied by old SSTables. It improves read performance by incrementally replacing old SSTables with...
compacted SSTables. Cassandra can read data directly from the new SSTable even before it finishes writing, instead of waiting for the entire compaction process to finish.

As Cassandra processes writes and reads, it replaces the old SSTables with new SSTables in the page cache. The process of caching the new SSTable, while directing reads away from the old one, is incremental — it does not cause a the dramatic cache miss. Cassandra provides predictable high performance even under heavy load.

Compaction strategies

Cassandra supports different compaction strategies, which control how which SSTables are chosen for compaction, and how the compacted rows are sorted into new SSTables. Each strategy has its own strengths. The sections that follow explain each of Cassandra’s compaction strategies.

Although each of the following sections starts with a generalized recommendation, many factors complicate the choice of a compaction strategy. See Which compaction strategy is best? (page 47).

**SizeTieredCompactionStrategy (STCS)**

Recommended for write-intensive workloads.

The SizeTieredCompactionStrategy (STCS) initiates compaction when Cassandra has accumulated a set number (default: 4) of similar-sized SSTables. STCS merges these SSTables into one larger SSTable. As these larger SSTables accumulate, STCS merges these into even larger SSTables. At any given time, several SSTables of varying sizes are present.

![Size tiered compaction after many inserts](image)

While STCS works well to compact a write-intensive workload, it makes reads slower because the merge-by-size process does not group data by rows. This makes it more likely that versions of a particular row may be spread over many SSTables. Also, STCS does not evict deleted data predictably because its trigger for compaction is SSTable size, and SSTables might not grow quickly enough to merge and evict old data. As the largest SSTables grow in size, the amount of disk space needed for both the new and old SSTables simultaneously during STCS compaction can outstrip a typical amount of disk space on a node.
• **Pros:** Compacts write-intensive workload very well.
• **Cons:** Can hold onto stale data too long. Amount of memory needed increases over time.

**LeveledCompactionStrategy (LCS)**

Recommended for read-intensive workloads.

The LeveledCompactionStrategy (LCS) alleviates some of the read operation issues with STCS. This strategy works with a series of levels. First, data in memtables is flushed to SSTables in the first level (L0). LCS compaction merges these first SSTables with larger SSTables in level L1.

Figure 4: Leveled compaction — adding SSTables

![Leveled compaction — adding SSTables](image)

The SSTables in levels greater than L1 are merged into SSTables with a size greater than or equal to `sstable_size_in_mb` (default: 160 MB). If a L1 SSTable stores data of a partition that is larger than L2, LCS moves the SSTable past L2 to the next level up.

Figure 5: Leveled compaction after many inserts

![Leveled compaction after many inserts](image)

In each of the levels above L0, LCS creates SSTables that are about the same size. Each level is 10X the size of the last level, so level L1 has 10X as many SSTables as L0, and level L2 has 100X as many. If the result of the compaction is more than 10 SSTables in level L1, the excess SSTables are moved to level L2.

The LCS compaction process guarantees that the SSTables within each level starting with L1 have non-overlapping data. For many reads, this process enables Cassandra to retrieve all the required data from only one or two SSTables. In fact, 90% of all reads can be satisfied from one SSTable. Since LCS does not compact
L0 tables, however, resource-intensive reads involving many L0 SSTables may still occur.

At levels beyond L0, LCS requires less disk space for compacting — generally, 10X the fixed size of the SSTable. Obsolete data is evicted more often, so deleted data uses smaller portions of the SSTables on disk. However, LCS compaction operations take place more often and place more I/O burden on the node. For write-intensive workloads, the payoff of using this strategy is generally not worth the performance loss to I/O operations. In many cases, tests of LCS-configured tables reveal I/O saturation on writes and compactions.

**Note:** Cassandra bypasses compaction operations when bootstrapping (page) a new node using LCS into a cluster. The original data is moved directly to the correct level because there is no existing data, so no partition overlap per level is present. For more information, see Apache Cassandra 2.2 - Bootstrapping Performance Improvements for Leveled Compaction.

- **Pros:** Disk requirements are easier to predict. Read operation latency is more predictable. Stale data is evicted more frequently.
- **Cons:** Much higher I/O utilization impacting operation latency

**TimeWindowCompactionStrategy (TWCS)**

Recommended for time series and expiring TTL workloads.

The TimeWindowCompactionStrategy (TWCS) is similar to DTCS with simpler settings. TWCS groups SSTables using a series of time windows. During compaction, TWCS applies STCS to uncompacted SSTables in the most recent time window. At the end of a time window, TWCS compacts all SSTables that fall into that time window into a single SSTable based on the SSTable maximum timestamp. Once the major compaction for a time window is completed, no further compaction of the data will ever occur. The process starts over with the SSTables written in the next time window.
Database internals

memtables are all flushed at 100MB in size

within the time window, SSTables are STCS compacted

when the time window passes all SSTables are compacted to one table

once the “active” window passes, SSTables are never compacted
As the figure shows, from 10 AM to 11 AM, the memtables are flushed from memory into 100MB SSTables. These SSTables are compacted into larger SSTables using STCS. At 11 AM, all these SSTables are compacted into a single SSTable, and never compacted again by TWCS. At 12 NOON, the new SSTables created between 11 AM and 12 NOON are compacted using STCS, and at the end of the time window the TWCS compaction repeats. Notice that each TWCS time window contains varying amounts of data.

**Note:** For an animated explanation, see the Datastax Academy Time Window Compaction Strategy video.

The TWCS configuration has two main property settings:

- **compaction_window_unit**: time unit used to define the window size (milliseconds, seconds, hours, and so on)
- **compaction_window_size**: how many units per window (1, 2, 3, and so on)

The configuration for the above example: `compaction_window_unit = 'minutes', compaction_window_size = 60`

**Pros**: Used for time series data, stored in tables that use the default TTL for all data. Simpler configuration than that of DTCS.

**Cons**: Not appropriate if out-of-sequence time data is required, since SSTables will not compact as well. Also, not appropriate for data without a TTL, as storage will grow without bound. Less fine-tuned configuration is possible than with DTCS.

**DateTieredCompactionStrategy (DTCS)**

Deprecated in Cassandra 3.0.8/3.8.

The DateTieredCompactionStrategy (DTCS) is similar to STCS. But instead of compacting based on SSTable size, DTCS compacts based on SSTable age. (Each column in an SSTable is marked with the timestamp at write time. As the age of an SSTable, DTCS uses the oldest (minimum) timestamp of any column the SSTable contains.)

Configuring the DTCS time window ensures that new and old data are not mixed in merged SSTables. In fact, using Time-To-Live (TTL) timestamps, DTCS can eject whole SSTables containing expired data. This strategy often generates similar-sized SSTables if time series data is ingested at a steady rate.

DTCS compacts SSTables into larger tables, as with STCS, when the system accumulates a configurable number of SSTables within a configurable time interval. However, DTCS skips compacting SSTables that reach a configurable age. This logic reduces the number of times data is rewritten. Queries that ask for data in a particular last time interval, such as an hour, can be executed very efficiently on DTCS-compacted SSTables (particularly if the requested time interval is coordinated with the configured interval for compaction).
One use case that can cause difficulty with this strategy is out-of-sequence writing. For example, an operation that writes a timestamped record with a timestamp outside the current time window. Read repairs can inject out-of-sequence timestamps, so be sure to turn off read repairs when using DTCS. For more information, see DateTieredCompactionStrategy: Notes from the Field.

- **Pros**: Specifically designed for time series data, stored in tables that use the default TTL. DTCS is a better choice when fine-tuning is required to meet space-related SLAs.

- **Cons**: Insertion of records out of time sequence (by repairs or hint replaying) can increase latency or cause errors. In some cases, it may be necessary to turn off read repair and carefully test and control the use of TIMESTAMP options in BATCH, DELETE, INSERT and UPDATE CQL commands.

Which compaction strategy is best?

To implement the best compaction strategy:

1. Review your application's requirements.

2. Configure the table to use the most appropriate strategy.

3. Test the compaction strategies against your data.

The following questions are based on the experiences of Cassandra developers and users with the strategies described above.

**Does your table process time series data?**

If so, your best choices are TWCS or DTCS. For details, read the descriptions on this page.

If your table is not focused on time series data, the choice becomes more complicated. The following questions introduce other considerations that may guide your choice.

**Does your table handle more reads than writes, or more writes than reads?**

LCS is a good choice if your table processes twice as many reads as writes or more – especially randomized reads. If the proportion of reads to writes is closer, the performance hit exacted by LCS may not be worth the benefit. Be aware that LCS can be quickly overwhelmed by a high volume of writes.

**Does the data in your table change often?**

One advantage of LCS is that it keeps related data in a small set of SSTables. If your data is immutable or not subject to frequent upserts (page), STCS accomplishes the same type of grouping without the LCS performance hit.

**Do you require predictable levels of read and write activity?**

LCS keeps the SSTables within predictable sizes and numbers. For example, if your table's read/write ratio is small, and it is expected to conform to a Service
Level Agreements (SLAs) for reads, it may be worth taking the write performance penalty of LCS in order to keep read rates and latency at predictable levels. And you may be able to overcome this write penalty through horizontal scaling (adding more nodes).

**Will your table be populated by a batch process?**
On both batch reads and batch writes, STCS performs better than LCS. The batch process causes little or no fragmentation, so the benefits of LCS are not realized; batch processes can overwhelm LCS-configured tables.

**Does your system have limited disk space?**
LCS handles disk space more efficiently than STCS: it requires about 10% headroom in addition to the space occupied by the data is handles. STCS and DTCS generally require, in some cases, as much as 50% more than the data space.

**Is your system reaching its limits for I/O?**
LCS is significantly more I/O intensive than DTCS or STCS. Switching to LCS may introduce extra I/O load that offsets the advantages.

**Testing compaction strategies**
Suggestions for determining which compaction strategy is best for your system:

- Create a three-node cluster using one of the compaction strategies, stress test the cluster using cassandra-stress, and measure the results.
- Set up a node on your existing cluster and use Cassandra's write survey mode to sample live data. See What's new in Cassandra 1.1: live traffic sampling.

**Configuring and running compaction**
Set the compaction strategy for a table in the parameters for the CREATE TABLE or ALTER TABLE command. For details, see Table properties (page ).

You can start compaction manually using the nodetool compact (page 257) command.

**More information about compaction**
The following blog posts and videos provide more information from developers that have tested compaction strategies:

- When to Use Leveled Compaction
- Leveled compaction in Apache Cassandra
- Using TimeWindowCompactionStrategy for Time Series Workloads
- DateTieredCompactionStrategy: Notes from the Field
- Date-Tiered Compaction in Cassandra
- DateTieredCompactionStrategy: Compaction for Time Series Data.
• What delays a tombstone purge when using LCS in Cassandra

How is data updated?

Cassandra treats each new row as an upsert (page 36): if the new row has the same primary key as that of an existing row, Cassandra processes it as an update to the existing row.

During a write (page 38), Cassandra adds each new row to the database without checking on whether a duplicate record exists. This policy makes it possible that many versions of the same row may exist in the database. For more details about writes, see How is data written? (page 38)

Periodically, the rows stored in memory are streamed to disk into structures called SSTables. At certain intervals, Cassandra compacts (page 41) smaller SSTables into larger SSTables. If Cassandra encounters two or more versions of the same row during this process, Cassandra only writes the most recent version to the new SSTable. After compaction, Cassandra drops the original SSTables, deleting the outdated rows.

Most Cassandra installations store replicas of each row on two or more nodes. Each node performs compaction independently. This means that even though out-of-date versions of a row have been dropped from one node, they may still exist on another node.

This is why Cassandra performs another round of comparisons during a read process (page 52). When a client requests data with a particular primary key, Cassandra retrieves many versions of the row from one or more replicas. The version with the most recent timestamp is the only one returned to the client ("last-write-wins").

Note: Some database operations may only write partial updates of a row, so some versions of a row may include some columns, but not all. During a compaction or write, Cassandra assembles a complete version of each row from the partial updates, using the most recent version of each column.

How is data deleted?

Cassandra's processes for deleting data are designed to improve performance, and to work with Cassandra's built-in properties for data distribution and fault-tolerance.

Cassandra treats a delete as an insert or upsert (page 36). The data being added to the partition in the DELETE (page 24) command is a deletion marker called a tombstone (page 131). The tombstones go through Cassandra's write path, and are written to SSTables on one or more nodes. The key difference feature of a tombstone: it has a built-in expiration date/time. At the end of its expiration period (for details see below) the tombstone is deleted as part of Cassandra's normal compaction (page 41) process.

You can also mark a Cassandra record (row or column) with a time-to-live (page 49) value. After this amount of time has ended, Cassandra marks the record with a tombstone, and handles it like other tombstoned records.
Deletion in a distributed system

In a multi-node cluster, Cassandra can store replicas of the same data on two or more nodes. This helps prevent data loss, but it complicates the delete process. If a node receives a delete for data it stores locally, the node tombstones the specified record and tries to pass the tombstone to other nodes containing replicas of that record. But if one replica node is unresponsive at that time, it does not receive the tombstone immediately, so it still contains the pre-delete version of the record. If the tombstoned record has already been deleted from the rest of the cluster before that node recovers, Cassandra treats the record on the recovered node as new data, and propagates it to the rest of the cluster. This kind of deleted but persistent record is called a zombie (page 311).

To prevent the reappearance of zombies, the database gives each tombstone a grace period. The purpose of the grace period is to give unresponsive nodes time to recover and process tombstones normally. When multiple replica answers are part of a read request, and those responses differ, then whichever values are most recent take precedence. For example, if a node has a tombstone but another node has a more recent change, then the final result includes the more recent change.

If a node has a tombstone and another node has only an older value for the record, then the final record will have the tombstone. If a client writes a new update to the tombstone during the grace period, the database overwrites the tombstone.

When an unresponsive node recovers, Cassandra uses hinted handoff (page 213) to replay the database mutations (page 281) the node missed while it was down. Cassandra does not replay a mutation for a tombstoned record during its grace period. But if the node does not recover until after the grace period ends, Cassandra may miss the deletion.

After the tombstone's grace period ends, Cassandra deletes the tombstone during compaction.

The grace period for a tombstone is set by the property gc_grace_seconds. Its default value is 864000 seconds (ten days). Each table can have its own value for this property.

More about Cassandra deletes

Details:

- The expiration date/time for a tombstone is the date/time of its creation plus the value of the table property gc_grace_seconds.
- Cassandra also supports Batch data insertion and updates (page 441). This procedure also introduces the danger of replaying a record insertion after that record has been removed from the rest of the cluster. Cassandra does not replay a batched mutation for a tombstoned record that is still within its grace period.
- On a single-node cluster, you can set gc_grace_seconds to 0 (zero).
- To completely prevent the reappearance of zombie records, run nodetool repair (page 311) on a node after it recovers, and on each table every gc_grace_seconds.
- If all records in a table are given a TTL at creation, and all are allowed to expire and not deleted manually, it is not necessary to run nodetool repair (page 311) for that table on a regular basis.
• If you use the `SizeTieredCompactionStrategy` or `DateTieredCompactionStrategy` *(page 40)*, you can delete expired tombstones immediately by manually starting the compaction process *(page 257)*.

  **Caution:** If you force compaction, Cassandra may create one very large SSTable from all the data. Cassandra will not trigger another compaction for a long time. The data in the SSTable created during the forced compaction can grow very stale during this long period of non-compaction.

• Cassandra allows you to set a `default_time_to_live` property *(page *) for an entire table. Columns and rows marked with regular TTLs are processed as described above; but when a record exceeds the table-level TTL, Cassandra deletes it immediately, without tombstoning or compaction.

• Cassandra supports immediate deletion through the `DROP KEYSPACE` *(page *) and `DROP TABLE` *(page *) statements.

**How are indexes stored and updated?**

Secondary indexes are used to filter a table for data stored in non-primary key columns. For example, a table storing cyclist names and ages using the last name of the cyclist as the primary key might have a secondary index on the age to allow queries by age. Querying to match a non-primary key column is an anti-pattern, as querying should always result in a continuous slice of data retrieved from the table.

![Secondary index example](image)

If the table rows are stored based on last names, the table may be spread across several partitions stored on different nodes. Queries based on a particular range of last names, such as all cyclists with the last name Matthews will retrieve sequential rows from the table, but a query based on the age, such as all cyclists who are 28, will require all nodes to be queried for a value. Non-primary keys play no role in ordering the data in storage, thus querying for a particular value of a non-primary key column results in scanning all partitions. Scanning all partitions generally results in a prohibitive read latency, and is not allowed.

Secondary indexes can be built for a column in a table. These indexes are stored locally on each node in a hidden table and built in a background process. If a secondary index is used in a query that is not restricted to a particular partition key, the query will have prohibitive read latency because all nodes will be queried. A query with these parameters is
only allowed if the query option `ALLOW FILTERING` is used. This option is not appropriate for production environments. If a query includes both a partition key condition and a secondary index column condition, the query will be successful because the query can be directed to a single node partition.

This technique, however, does not guarantee trouble-free indexing, so know when and when not to use an index. In the example shown above, an index on the age could be used, but a better solution is to create a materialized view or additional table that is ordered by age.

As with relational databases, keeping indexes up to date uses processing time and resources, so unnecessary indexes should be avoided. When a column is updated, the index is updated as well. If the old column value still exists in the memtable, which typically occurs when updating a small set of rows repeatedly, Cassandra removes the corresponding obsolete index entry; otherwise, the old entry remains to be purged by compaction. If a read sees a stale index entry before compaction purges it, the reader thread invalidates it.

**How is data read?**

To satisfy a read, Cassandra must combine results from the active memtable and potentially multiple SSTables.

Cassandra processes data at several stages on the read path to discover where the data is stored, starting with the data in the memtable and finishing with SSTables:

- Check the memtable
- Check row cache, if enabled
- Checks Bloom filter
- Checks partition key cache, if enabled
- Goes directly to the compression offset map if a partition key is found in the partition key cache, or checks the partition summary if not

  If the partition summary is checked, then the partition index is accessed

- Locates the data on disk using the compression offset map
- Fetches the data from the SSTable on disk
Memtable

If the memtable has the desired partition data, then the data is read and then merged with the data from the SSTables. The SSTable data is accessed as shown in the following steps.

Row Cache

Typical of any database, reads are fastest when the most in-demand data fits into memory. The operating system page cache is best at improving performance, although the row cache can provide some improvement for very read-intensive operations, where read operations are 95% of the load. Row cache is contra-indicated for write-intensive operations. The row cache, if enabled, stores a subset of the partition data stored on disk in the SSTables in memory. In Cassandra 2.2 and later, it is stored in fully off-heap memory using a new implementation that relieves garbage collection pressure in the JVM. The subset stored in the row cache use a configurable amount of memory for a specified period of time. The row
Database internals

cache uses LRU (least-recently-used) eviction to reclaim memory when the cache has filled up.

The row cache size is configurable, as is the number of rows to store. Configuring the number of rows to be stored is a useful feature, making a "Last 10 Items" query very fast to read. If row cache is enabled, desired partition data is read from the row cache, potentially saving two seeks to disk for the data. The rows stored in row cache are frequently accessed rows that are merged and saved to the row cache from the SSTables as they are accessed. After storage, the data is available to later queries. The row cache is not write-through. If a write comes in for the row, the cache for that row is invalidated and is not cached again until the row is read. Similarly, if a partition is updated, the entire partition is evicted from the cache. When the desired partition data is not found in the row cache, then the Bloom filter (page ) is checked.

Bloom Filter

First, Cassandra checks the Bloom filter to discover which SSTables are likely to have the request partition data. The Bloom filter is stored in off-heap memory. Each SSTable has a Bloom filter associated with it. A Bloom filter can establish that a SSTable does not contain certain partition data. A Bloom filter can also find the likelihood that partition data is stored in a SSTable. It speeds up the process of partition key lookup by narrowing the pool of keys. However, because the Bloom filter is a probabilistic function, it can result in false positives. Not all SSTables identified by the Bloom filter will have data. If the Bloom filter does not rule out an SSTable, Cassandra checks the partition key cache (page 237).

The Bloom filter grows to approximately 1-2 GB per billion partitions. In the extreme case, you can have one partition per row, so you can easily have billions of these entries on a single machine. The Bloom filter is tunable if you want to trade memory for performance.

Partition Key Cache

The partition key cache, if enabled, stores a cache of the partition index in off-heap memory. The key cache uses a small, configurable amount of memory, and each "hit" saves one seek during the read operation. If a partition key is found in the key cache can go directly to the compression offset map to find the compressed block on disk that has the data. The partition key cache functions better once warmed, and can greatly improve over the performance of cold-start reads, where the key cache doesn’t yet have or has purged the keys stored in the key cache. It is possible to limit the number of partition keys saved in the key cache, if memory is very limited on a node. If a partition key is not found in the key cache, then the partition summary (page ) is searched.

The partition key cache size is configurable, as are the number of partition keys to store in the key cache.

Partition Summary

The partition summary is an off-heap in-memory structure that stores a sampling of the partition index. A partition index contains all partition keys, whereas a partition summary samples every X keys, and maps the location of every Xth key's location in the index file. For example, if the partition summary is set to sample every 20 keys, it will store the location of the first key as the beginning of the SSTable file, the 20th key and its location in the file, and
so on. While not as exact as knowing the location of the partition key, the partition summary can shorten the scan to find the partition data location. After finding the range of possible partition key values, the partition index (page 72) is searched.

By configuring the sample frequency, you can trade memory for performance, as the more granularity the partition summary has, the more memory it will use. The sample frequency is changed using the index interval (page 98) property in the table definition. A fixed amount of memory is configurable using the index_summary_capacity_in_mb (page 98) property, and defaults to 5% of the heap size.

Partition Index

The partition index resides on disk and stores an index of all partition keys mapped to their offset. If the partition summary has been checked for a range of partition keys, now the search passes to the partition index to seek the location of the desired partition key. A single seek and sequential read of the columns over the passed-in range is performed. Using the information found, the partition index now goes to the compression offset map to find the compressed block on disk that has the data. If the partition index must be searched, two seeks to disk will be required to find the desired data.

Compression offset map

The compression offset map stores pointers to the exact location on disk that the desired partition data will be found. It is stored in off-heap memory and is accessed by either the partition key cache or the partition index. The desired compressed partition data is fetched from the correct SSTable(s) once the compression offset map identifies the disk location. The query receives the result set.

**Note:** Within a partition, all rows are not equally expensive to query. The very beginning of the partition (the first rows, clustered by your key definition) is slightly less expensive to query because there is no need to consult the partition-level index.

The compression offset map grows to 1-3 GB per terabyte compressed. The more you compress data, the greater number of compressed blocks you have and the larger the compression offset table. Compression is enabled by default even though going through the compression offset map consumes CPU resources. Having compression enabled makes the page cache more effective, and typically, almost always pays off.

**How do write patterns affect reads?**

It is important to consider how the write operations will affect the read operations in the cluster. The type of compaction strategy (page 40) Cassandra performs on your data is configurable and can significantly affect read performance. Using the SizeTieredCompactionStrategy or DateTieredCompactionStrategy tends to cause data...
fragmentation when rows are frequently updated. The LeveledCompactionStrategy (LCS) was designed to prevent fragmentation under this condition.

Data consistency

How are consistent read and write operations handled?

Consistency refers to how up-to-date and synchronized all replicas of a row of Cassandra data are at any given moment. Ongoing repair operations (page 212) in Cassandra ensure that all replicas of a row will eventually be consistent. Repairs work to decrease the variability in replica data, but constant data traffic through a widely distributed system can lead to inconsistency (stale data) at any given time. Cassandra is a AP system according to the CAP theorem, providing high availability and partition tolerance. Cassandra does have flexibility in its configuration, though, and can perform more like a CP (consistent and partition tolerant) system according to the CAP theorem, depending on the application requirements. Two consistency features are tunable consistency and linearizable consistency.

Tunable consistency

To ensure that Cassandra can provide the proper levels of consistency for its reads and writes, Cassandra extends the concept of eventual consistency by offering tunable consistency. You can tune Cassandra's consistency level per-operation, or set it globally for a cluster or datacenter. You can vary the consistency for individual read or write operations so that the data returned is more or less consistent, as required by the client application. This allows you to make Cassandra act more like a CP (consistent and partition tolerant) or AP (highly available and partition tolerant) system according to the CAP theorem, depending on the application requirements.

**Note:** It is not possible to "tune" Cassandra into a completely CA system. See You Can't Sacrifice Partition Tolerance for a more detailed discussion.

There is a tradeoff between operation latency and consistency: higher consistency incurs higher latency, lower consistency permits lower latency. You can control latency by tuning consistency.

The consistency level determines the number of replicas that need to acknowledge the read or write operation success to the client application. For read operations, the read consistency level specifies how many replicas must respond to a read request before returning data to the client application. If a read operation reveals inconsistency among replicas, Cassandra initiates a read repair (page 215) to update the inconsistent data.

For write operations, the write consistency level specified how many replicas must respond to a write request before the write is considered successful. Even at low consistency levels, Cassandra writes to all replicas of the partition key, including replicas in other datacenters. The write consistency level just specifies when the coordinator can report to the client application that the write operation is considered completed. Write operations will use
hinted handoffs (page 213) to ensure the writes are completed when replicas are down or otherwise not responsive to the write request.

Typically, a client specifies a consistency level that is less than the replication factor specified by the keyspace. Another common practice is to write at a consistency level of QUORUM and read at a consistency level of QUORUM. The choices made depend on the client application's needs, and Cassandra provides maximum flexibility for application design.

Linearizable consistency

In ACID terms, linearizable consistency (or serial consistency) is a serial (immediate) isolation level for lightweight transactions (page 59). Cassandra does not use employ traditional mechanisms like locking or transactional dependencies when concurrently updating multiple rows or tables.

However, some operations must be performed in sequence and not interrupted by other operations. For example, duplications or overwrites in user account creation can have serious consequences. Situations like race conditions (two clients updating the same record) can introduce inconsistency across replicas. Writing with high consistency does nothing to reduce this. You can apply linearizable consistency to a unique identifier, like the userID or email address, although is not required for all aspects of the user's account. Serial operations for these elements can be implemented in Cassandra with the Paxos consensus protocol, which uses a quorum-based algorithm. Lightweight transactions can be implemented without the need for a master database or two-phase commit process.

Lightweight transaction write operations use the serial consistency level for Paxos consensus and the regular consistency level for the write to the table. For more information, see Lightweight Transactions (page 59).

Calculating consistency

Reliability of read and write operations depends on the consistency used to verify the operation. Strong consistency can be guaranteed when the following condition is true:

\[ R + W > N \]

where

- \( R \) is the consistency level of read operations
- \( W \) is the consistency level of write operations
- \( N \) is the number of replicas

If the replication factor is 3, then the consistency level of the reads and writes combined must be at least 4. For example, read operations using 2 out of 3 replicas to verify the value, and write operations using 2 out of 3 replicas to verify the value will result in strong consistency. If fast write operations are required, but strong consistency is still desired, the write consistency level is lowered to 1, but now read operations have to verify a matched value on all 3 replicas. Writes will be fast, but reads will be slower.

Eventual consistency occurs if the following condition is true:
R + W =< N

where

- R is the consistency level of read operations
- W is the consistency level of write operations
- N is the number of replicas

If the replication factor is 3, then the consistency level of the reads and writes combined are 3 or less. For example, read operations using QUORUM (page 64) (2 out of 3 replicas) to verify the value, and write operations using ONE (1 out of 3 replicas) to do fast writes will result in eventual consistency. All replicas will receive the data, but read operations are more vulnerable to selecting data before all replicas write the data.

Additional consistency examples:

- You do a write at ONE, the replica crashes one second later. The other messages are not delivered. The data is lost.
- You do a write at ONE, and the operation times out. Future reads can return the old or the new value. You will not know the data is incorrect.
- You do a write at ONE, and one of the other replicas is down. The node comes back online. The application will get old data from that node until the node gets the correct data or a read repair occurs.
- You do a write at QUORUM, and then a read at QUORUM. One of the replicas dies. You will always get the correct data.

**How are Cassandra transactions different from RDBMS transactions?**

Cassandra does not use RDBMS ACID transactions with rollback or locking mechanisms, but instead offers atomic, isolated, and durable transactions with eventual/tunable consistency that lets the user decide how strong or eventual they want each transaction’s consistency to be.

As a non-relational database, Cassandra does not support joins or foreign keys, and consequently does not offer consistency in the ACID sense. For example, when moving money from account A to B the total in the accounts does not change. Cassandra supports atomicity and isolation at the row-level, but trades transactional isolation and atomicity for high availability and fast write performance. Cassandra writes are durable.

**Atomicity**

In Cassandra, a write operation is atomic at the partition level, meaning the insertions or updates of two or more rows in the same partition are treated as one write operation. A delete operation is also atomic at the partition level.

For example, if using a write consistency level of QUORUM with a replication factor of 3, Cassandra will replicate the write to all nodes in the cluster and wait for acknowledgement from two nodes. If the write fails on one of the nodes but succeeds on the other, Cassandra
Database internals

reports a failure to replicate the write on that node. However, the replicated write that succeeds on the other node is not automatically rolled back.

Cassandra uses client-side timestamps to determine the most recent update to a column. The latest timestamp always wins when requesting data, so if multiple client sessions update the same columns in a row concurrently, the most recent update is the one seen by readers.

Isolation

Cassandra write and delete operations are performed with full row-level isolation. This means that a write to a row within a single partition on a single node is only visible to the client performing the operation – the operation is restricted to this scope until it is complete. All updates in a batch operation belonging to a given partition key have the same restriction. However, a Batch operation is not isolated if it includes changes to more than one partition.

Durability

Writes in Cassandra are durable. All writes to a replica node are recorded both in memory and in a commit log on disk before they are acknowledged as a success. If a crash or server failure occurs before the memtables are flushed to disk, the commit log is replayed on restart to recover any lost writes. In addition to the local durability (data immediately written to disk), the replication of data on other nodes strengthens durability.

You can manage the local durability to suit your needs for consistency using the commitlog_sync (page 95) option in the cassandra.yaml file. Set the option to either periodic or batch.

The location of the cassandra.yaml (page ) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>

<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

How do I accomplish lightweight transactions with linearizable consistency?

Distributed databases present a unique challenge when data must be strictly read and written in sequential order. In transactions for creating user accounts or transferring money, race conditions between two potential writes must be regulated to ensure that one write precedes the other. In Cassandra, the Paxos consensus protocol is used to implement lightweight transactions that can handle concurrent operations.

The Paxos protocol is implemented in Cassandra with linearizable consistency, that is sequential consistency with real-time constraints. Linearizable consistency ensures transaction isolation at a level similar to the serializable level offered by RDBMSs. This type of transaction is known as compare and set (CAS); replica data is compared and any data found to be out of date is set to the most consistent value. In Cassandra, the process
combines the Paxos protocol with normal read and write operations to accomplish the compare and set operation.

The Paxos protocol is implemented as a series of phases:

1. Prepare/Promise
2. Read/Results
3. Propose/Accept
4. Commit/Acknowledge

These phases are actions that take place between a proposer and acceptors. Any node can be a proposer, and multiple proposers can be operating at the same time. For simplicity, this description will use only one proposer. A proposer prepares by sending a message to a quorum of acceptors that includes a proposal number. Each acceptor promises to accept the proposal if the proposal number is the highest they have received. Once the proposer receives a quorum of acceptors who promise, the value for the proposal is read from each acceptor and sent back to the proposer. The proposer figures out which value to use and proposes the value to a quorum of the acceptors along with the proposal number. Each acceptor accepts the proposal with a certain number if and only if the acceptor is not already promised to a proposal with a high number. The value is committed and acknowledged as a Cassandra write operation if all the conditions are met.

These four phases require four round trips between a node proposing a lightweight transaction and any cluster replicas involved in the transaction. Performance will be affected. Consequently, reserve lightweight transactions for situations where concurrency must be considered.

Lightweight transactions will block other lightweight transactions from occurring, but will not stop normal read and write operations from occurring. Lightweight transactions use a timestamping mechanism different than for normal operations and mixing LWTS and normal operations can result in errors. If lightweight transactions are used to write to a row within a partition, only lightweight transactions for both read and write operations should be used. This caution applies to all operations, whether individual or batched. For example, the following series of operations can fail:

```
DELETE ...
INSERT .... IF NOT EXISTS
SELECT ....
```

The following series of operations will work:

```
DELETE ... IF EXISTS
INSERT .... IF NOT EXISTS
SELECT .....
Reads with linearizable consistency

A SERIAL consistency level (page 61) allows reading the current (and possibly uncommitted) state of data without proposing a new addition or update. If a SERIAL read finds an uncommitted transaction in progress, Cassandra performs a read repair (page ) as part of the commit.

How do I discover consistency level performance?

Before changing the consistency level on read and write operations, discover how your CQL commands are performing using the TRACING command in CQL. Using cqlsh, you can vary the consistency level and trace read and write operations. The tracing output includes latency times for the operations.

The CQL documentation includes a tutorial (page ) comparing consistency levels.

Tip: For more information on tracing data, see this post on the DataStax Support Blog, which explains in detail how to locate data on disk.

How is the consistency level configured?

Consistency levels in Cassandra can be configured to manage availability versus data accuracy. Configure consistency for a session or per individual read or write operation. Within cqlsh, use CONSISTENCY (page ), to set the consistency level for all queries in the current cqlsh session. For programming client applications, set the consistency level using an appropriate driver. For example, using the Java driver, call QueryBuilder.insertInto with setConsistencyLevel to set a per-insert consistency level.

The consistency level defaults to ONE for all write and read operations.

Write consistency levels

This table describes the write consistency levels in strongest-to-weakest order.

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>A write must be written to the commit log and memtable (page 39) on all replica nodes in the cluster for that partition.</td>
<td>Provides the highest consistency and the lowest availability of any other level.</td>
</tr>
<tr>
<td>Level</td>
<td>Description</td>
<td>Usage</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>EACH QUORUM</td>
<td>Strong consistency. A write must be written to the commit log and memtable on a quorum of replica nodes in each datacenter.</td>
<td>Used in multiple datacenter clusters to strictly maintain consistency at the same level in each datacenter. For example, choose this level if you want a read to fail when a datacenter is down and the QUORUM cannot be reached on that datacenter.</td>
</tr>
<tr>
<td>QUORUM</td>
<td>A write must be written to the commit log and memtable on a quorum of replica nodes across all datacenters.</td>
<td>Used in either single or multiple datacenter clusters to maintain strong consistency across the cluster. Use if you can tolerate some level of failure.</td>
</tr>
<tr>
<td>LOCAL QUORUM</td>
<td>Strong consistency. A write must be written to the commit log and memtable on a quorum of replica nodes in the same datacenter as the coordinator.</td>
<td>Used in multiple datacenter clusters with a rack-aware replica placement strategy, such as NetworkTopologyStrategy, and a properly configured snitch. Use to maintain consistency locally (within the single datacenter). Can be used with SimpleStrategy.</td>
</tr>
<tr>
<td>ONE</td>
<td>A write must be written to the commit log and memtable of at least one replica node.</td>
<td>Satisfies the needs of most users because consistency requirements are not stringent.</td>
</tr>
<tr>
<td>TWO</td>
<td>A write must be written to the commit log and memtable of at least two replica nodes.</td>
<td>Similar to ONE.</td>
</tr>
<tr>
<td>THREE</td>
<td>A write must be written to the commit log and memtable of at least three replica nodes.</td>
<td>Similar to TWO.</td>
</tr>
<tr>
<td>LOCAL ONE</td>
<td>A write must be sent to, and successfully acknowledged by, at least one replica node in the local datacenter.</td>
<td>In a multiple datacenter clusters, a consistency level of ONE is often desirable, but cross-DC traffic is not. LOCAL ONE accomplishes this. For security and quality reasons, you can use this consistency level in an offline datacenter to prevent automatic connection to online nodes in other datacenters if an offline node goes down.</td>
</tr>
</tbody>
</table>
### Database internals

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANY</td>
<td>A write must be written to at least one node. If all replica nodes for the given partition key are down, the write can still succeed after a hinted handoff (<a href="#">page 213</a>) has been written. If all replica nodes are down at write time, an ANY write is not readable until the replica nodes for that partition have recovered.</td>
<td>Provides low latency and a guarantee that a write never fails. Delivers the lowest consistency and highest availability.</td>
</tr>
</tbody>
</table>

**Read consistency levels**

This table describes read consistency levels in strongest-to-weakest order.

### Table 2: Read Consistency Levels

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Returns the record after all replicas have responded. The read operation will fail if a replica does not respond.</td>
<td>Provides the highest consistency of all levels and the lowest availability of all levels.</td>
</tr>
<tr>
<td>EACH_QUORUM</td>
<td>Not supported for reads.</td>
<td></td>
</tr>
<tr>
<td>QUORUM</td>
<td>Returns the record after a quorum of replicas from all datacenters (<a href="#">page </a>) has responded.</td>
<td>Used in either single or multiple datacenter clusters to maintain strong consistency across the cluster. Ensures strong consistency if you can tolerate some level of failure.</td>
</tr>
<tr>
<td>LOCAL_QUORUM</td>
<td>Returns the record after a quorum of replicas in the current datacenter as the coordinator (<a href="#">page </a>) has reported. Avoids latency of inter-datacenter communication.</td>
<td>Used in multiple datacenter clusters with a rack-aware replica placement strategy (<a href="#">NetworkTopologyStrategy</a>) and a properly configured snitch. Fails when using <a href="#">SimpleStrategy</a>.</td>
</tr>
<tr>
<td>ONE</td>
<td>Returns a response from the closest replica, as determined by the snitch (<a href="#">page 28</a>). By default, a read repair (<a href="#">page </a>) runs in the background to make the other replicas consistent.</td>
<td>Provides the highest availability of all the levels if you can tolerate a comparatively high probability of stale data being read. The replicas contacted for reads may not always have the most recent write.</td>
</tr>
<tr>
<td>TWO</td>
<td>Returns the most recent data from two of the closest replicas.</td>
<td>Similar to ONE.</td>
</tr>
<tr>
<td>THREE</td>
<td>Returns the most recent data from three of the closest replicas.</td>
<td>Similar to TWO.</td>
</tr>
<tr>
<td>LOCAL_ONE</td>
<td>Returns a response from the closest replica in the local datacenter.</td>
<td>Same usage as described in the table about write consistency levels.</td>
</tr>
</tbody>
</table>
### Database internals

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERIAL</td>
<td>Allows reading the current (and possibly uncommitted [page 39]) state of data without proposing a new addition or update. If a SERIAL read finds an uncommitted transaction in progress, it will commit the transaction as part of the read. Similar to QUORUM.</td>
<td>To read the latest value of a column after a user has invoked a lightweight transaction [page 59] to write to the column, use SERIAL. Cassandra then checks the inflight lightweight transaction for updates and, if found, returns the latest data.</td>
</tr>
<tr>
<td>LOCAL_SERIAL</td>
<td>Same as SERIAL, but confined to the datacenter. Similar to LOCAL_QUORUM.</td>
<td>Used to achieve linearizable consistency [page 57] for lightweight transactions.</td>
</tr>
</tbody>
</table>

### How QUORUM is calculated

The QUORUM level writes to the number of nodes that make up a quorum. A quorum is calculated, and then rounded down to a whole number, as follows:

\[
\text{quorum} = \left( \frac{\text{sum of replication factors}}{2} \right) + 1
\]

The sum of all the replication_factor settings for each datacenter is the sum of replication_factors.

\[
\text{sum of replication factors} = \text{datacenter1}_RF + \text{datacenter2}_RF + \ldots + \text{datacenter}_n_RF
\]

**Examples:**
- Using a replication factor of 3, a quorum is 2 nodes. The cluster can tolerate 1 replica down.
- Using a replication factor of 6, a quorum is 4. The cluster can tolerate 2 replicas down.
- In a two datacenter cluster where each datacenter has a replication factor of 3, a quorum is 4 nodes. The cluster can tolerate 2 replica nodes down.
- In a five datacenter cluster where two datacenters have a replication factor of 3 and three datacenters have a replication factor of 2, a quorum is 7 nodes.

The more datacenters, the higher number of replica nodes need to respond for a successful operation.

Similar to QUORUM, the LOCAL_QUORUM level is calculated based on the replication factor of the same datacenter as the coordinator node. That is, even if the cluster has more than one datacenter, the quorum is calculated only with local replica nodes.

In EACH_QUORUM, every datacenter in the cluster must reach a quorum based on that datacenter's replication factor in order for the write request to succeed. That is, for every datacenter in the cluster a quorum of replica nodes must respond to the coordinator node in order for the write request to succeed.
Configuring client consistency levels

You can use a `cqlsh` command, `CONSISTENCY (page 57)`, to set the consistency level for queries in the current `cqlsh` session. For programming client applications, set the consistency level using an appropriate driver. For example, call `QueryBuilder.insertInto` with a `setConsistencyLevel` argument using the Java driver.

**How is the serial consistency level configured?**

Serial consistency levels in Cassandra can be configured to manage lightweight transaction isolation. Lightweight transactions have two consistency levels defined. The serial consistency level defines the consistency level of the serial phase, or Paxos phase, of lightweight transactions. The learn phase, which defines what read operations will be guaranteed to complete immediately if lightweight writes are occurring uses a normal consistency level. The serial consistency level is ignored for any query that is not a conditional update.

**Serial consistency levels**

**Table 3: Serial Consistency Levels**

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERIAL</td>
<td>Achieves linearizable consistency (page 57) for lightweight transactions by preventing unconditional updates.</td>
<td>This consistency level is only for use with lightweight transaction. Equivalent to QUORUM.</td>
</tr>
<tr>
<td>LOCAL_SERIAL</td>
<td>Same as SERIAL but confined to the datacenter. A conditional write must be written to the commit log and memtable (page 39) on a quorum of replica nodes in the same datacenter.</td>
<td>Same as SERIAL but used to maintain consistency locally (within the single datacenter). Equivalent to LOCAL_QUORUM.</td>
</tr>
</tbody>
</table>

**How are read requests accomplished?**

There are three types of read requests that a coordinator (page 59) can send to a replica:

- A direct read request
- A digest request
- A background read repair request

In a direct read request, the coordinator node contacts one replica node. Then the coordinator sends a digest request to a number of replicas determined by the consistency level (page 56) specified by the client. The digest request checks the data in the replica node to make sure it is up to date. Then the coordinator sends a digest request to all remaining replicas. If any replica nodes have out of date data, a background read repair (page 215) request is sent. Read repair requests ensure that the requested row is made consistent on all replicas involved in a read query.
For a digest request the coordinator first contacts the replicas specified by the consistency level. The coordinator sends these requests to the replicas that currently respond the fastest. The contacted nodes respond with a digest of the requested data; if multiple nodes are contacted, the rows from each replica are compared in memory for consistency. If they are not consistent, the replica having the most recent data (based on the timestamp) is used by the coordinator to forward the result back to the client. To ensure that all replicas have the most recent version of the data, read repair is carried out to update out-of-date replicas.

For illustrated examples of read requests, see Examples of read consistency levels (page 66).

Rapid read protection using speculative_retry

Rapid read protection allows Cassandra to still deliver read requests when the originally selected replica nodes are either down or taking too long to respond. If the table has been configured with the speculative_retry (page ) property, the coordinator node for the read request will retry the request with another replica node if the original replica node exceeds a configurable timeout value to complete the read request.

Figure 9: Recovering from replica node failure with rapid read protection

The following diagrams show examples of read requests using these consistency levels:
• QUORUM in a single datacenter (page 67)
• ONE in a single datacenter (page 68)
• QUORUM in two datacenters (page 69)
• LOCAL_QUORUM in two datacenters (page 71)
• ONE in two datacenters (page 73)
• LOCAL_ONE in two datacenters (page 75)

Rapid read protection diagram (page 66) shows how the speculative retry table property affects consistency.

Example: A single datacenter cluster with a consistency level of QUORUM

In a single datacenter cluster with a replication factor of 3, and a read consistency level of QUORUM, 2 of the 3 replicas for the given row must respond to fulfill the read request. If the contacted replicas have different versions of the row, the replica with the most recent version will return the requested data. In the background, the third replica is checked for consistency with the first two, and if needed, a read repair is initiated for the out-of-date replicas.
Figure 10: Single datacenter cluster with 3 replica nodes and consistency set to QUORUM

Example: A single datacenter cluster with a consistency level of **ONE**

In a single datacenter cluster with a replication factor of 3, and a read consistency level of **ONE**, the closest replica for the given row is contacted to fulfill the read request. In the background a read repair is potentially initiated, based on the read_repair_chance setting of the table, for the other replicas.
Figure 11: Single datacenter cluster with 3 replica nodes and consistency set to ONE

Example: A two datacenter cluster with a consistency level of QUORUM

In a two datacenter cluster with a replication factor of 3, and a read consistency of QUORUM, 4 replicas for the given row must respond to fulfill the read request. The 4 replicas can be from any datacenter. In the background, the remaining replicas are checked for consistency with the first four, and if needed, a read repair is initiated for the out-of-date replicas.
Figure 12: Multiple datacenter cluster with 3 replica nodes and consistency level set to QUORUM
Example: A two datacenter cluster with a consistency level of `LOCAL_QUORUM`

In a multiple datacenter cluster with a replication factor of 3, and a read consistency of `LOCAL_QUORUM`, 2 replicas in the same datacenter as the coordinator node for the given row must respond to fulfill the read request. In the background, the remaining replicas are checked for consistency with the first 2, and if needed, a read repair is initiated for the out-of-date replicas.
Figure 13: Multiple datacenter cluster with 3 replica nodes and consistency set to LOCAL_QUORUM
Example: A two datacenter cluster with a consistency level of ONE

In a multiple datacenter cluster with a replication factor of 3, and a read consistency of ONE, the closest replica for the given row, regardless of datacenter, is contacted to fulfill the read request. In the background a read repair is potentially initiated, based on the `read_repair_chance` setting of the table, for the other replicas.
Figure 14: Multiple datacenter cluster with 3 replica nodes and consistency set to ONE
Example: A two datacenter cluster with a consistency level of \texttt{LOCAL\_ONE}

In a multiple datacenter cluster with a replication factor of 3, and a read consistency of \texttt{LOCAL\_ONE}, the closest replica for the given row in the same datacenter as the coordinator node is contacted to fulfill the read request. In the background a read repair is potentially initiated, based on the \texttt{read\_repair\_chance} setting of the table, for the other replicas.
How are write requests accomplished?

The coordinator sends a write request to all replicas that own the row being written. As long as all replica nodes are up and available, they will get the write regardless of the consistency
level (page 61) specified by the client. The write consistency level determines how many replica nodes must respond with a success acknowledgment in order for the write to be considered successful. Success means that the data was written to the commit log and the memtable as described in how data is written (page 38).

The coordinator node forwards the write to replicas of that row, and responds to the client once it receives write acknowledgments from the number of nodes specified by the consistency level. Exceptions:

- If the coordinator cannot write to enough replicas to meet the requested consistency level, it throws an Unavailable Exception and does not perform any writes.
- If there are enough replicas available but the required writes don't finish within the timeout window, the coordinator throws a Timeout Exception.

For example, in a single datacenter 10-node cluster with a replication factor of 3, an incoming write will go to all 3 nodes that own the requested row. If the write consistency level specified by the client is ONE, the first node to complete the write responds back to the coordinator, which then proxies the success message back to the client. A consistency level of ONE means that it is possible that 2 of the 3 replicas can miss the write if they happen to be down at the time the request is made. If a replica misses a write, the row is made consistent later using one of the built-in repair mechanisms (page 212): hinted handoff, read repair, or anti-entropy node repair.

Figure 16: Single datacenter cluster with 3 replica nodes and consistency set to ONE

Multiple datacenter write requests

In multiple datacenter deployments, Cassandra optimizes write performance by choosing one coordinator node. The coordinator node contacted by the client application forwards
the write request to one replica in each of the other datacenters, with a special tag to forward the write to the other local replicas.

If the write consistency level (page 56) is `LOCAL_ONE` or `LOCAL_QUORUM`, only the nodes in the same datacenter as the coordinator node must respond to the client request in order for the request to succeed. Use either `LOCAL_ONE` or `LOCAL_QUORUM` to reduce geographical latency lessen the impact on client write request response times.

Figure 17: Multiple datacenter cluster with 3 replica nodes and consistency set to QUORUM
Planning a cluster deployment

Planning has moved to Planning and testing cluster deployments (page ).
Installing Apache Cassandra 3.0

DataStax Enterprise (DSE) 5.0 includes an enhanced version of Apache Cassandra™. To download and install open-source Cassandra, see Apache Cassandra™.

Installing the Apache Cassandra 3.0 on RHEL-based systems

DataStax Enterprise (DSE) 5.0 includes an enhanced version of Apache Cassandra™. To download and install open-source Cassandra, see Apache Cassandra™.

Installing Apache Cassandra 3.0 on Debian-based systems

DataStax Enterprise (DSE) 5.0 includes an enhanced version of Apache Cassandra™. To download and install open-source Cassandra, see Apache Cassandra™.

Installing Apache Cassandra 3.0 on any Linux-based platform

DataStax Enterprise (DSE) 5.0 includes an enhanced version of Apache Cassandra™. To download and install open-source Cassandra, see Apache Cassandra™.

Installing earlier releases of Apache Cassandra 3.0

DataStax Enterprise (DSE) 5.0 includes an enhanced version of Apache Cassandra™. To download and install open-source Cassandra, see Apache Cassandra™.

Uninstalling Apache Cassandra 3.0

DataStax Enterprise (DSE) 5.0 includes an enhanced version of Apache Cassandra™. For instructions on uninstalling, see the Apache Cassandra™ documentation.

Installing on cloud providers

You can install Apache Cassandra on cloud providers that supply any of the supported platforms.

DataStax ComboAMI
DataStax no longer hosts the DataStax ComboAMI. You can install Cassandra by creating your instances using an AMI for a supported platform and from a trusted source. Then follow the instructions for your platform on Apache Cassandra™.

### Installing the JDK

#### Installing Oracle JDK on RHEL-based Systems

Configure your operating system to use the latest version of Oracle Java Platform, Standard Edition 8.

1. Check which version of the JDK your system is using:

   ```
   $ java -version
   ```

   If Oracle Java is used, the results should look like:

   ```
   java version "1.8.0_65"
   Java(TM) SE Runtime Environment (build 1.8.0_65-b17)
   Java HotSpot(TM) 64-Bit Server VM (build 25.65-b01, mixed mode)
   ```

2. If necessary, go to Oracle Java SE Downloads, accept the license agreement, and download the installer for your distribution.

   **Note:** If installing the Oracle JDK in a cloud environment, accept the license agreement, download the installer to your local client, and then use `scp` (secure copy) to transfer the file to your cloud machines.

3. From the directory where you downloaded the package, run the install:

   ```
   $ sudo rpm -ivh jdk-8uversion-linux-x64.rpm
   ```

   The RPM installs the JDK into the `/usr/java/` directory.

4. Set your system to use the Oracle JDK:

   ```
   $ sudo alternatives --install /usr/bin/java java /usr/java/jdk1.8.0_version/bin/java 200000
   ```

5. Use the `alternatives` command to switch to the Oracle JDK.

   ```
   $ sudo alternatives --config java
   ```

   **Note:** If you have trouble, you may need to set JAVA_HOME and PATH in your profile, such as `.bash_profile`. 

---

Apache Cassandra 3.0 for DSE 5.0 (Earlier version)
The following examples assume that the JDK is in /usr/java and which java shows /usr/bin/java:

- Shell or bash:
  
  ```bash
  $ export JAVA_HOME=/usr/java/latest
  $ export PATH=$JAVA_HOME/bin:$PATH
  ```

- C shell (csh):
  
  ```bash
  $ setenv JAVA_HOME "/usr/java/latest"
  $ setenv PATH $JAVA_HOME/bin:$PATH
  ```

6. Make sure your system is using the correct JDK:

```bash
$ java -version
```

```text
java version "1.8.0_65"
Java(TM) SE Runtime Environment (build 1.8.0_65-b17)
Java HotSpot(TM) 64-Bit Server VM (build 25.65-b01, mixed mode)
```

**Installing Oracle JDK on Debian or Ubuntu systems**

Configure your operating system to use the latest version of Oracle Java Platform, Standard Edition 8.

The Oracle Java Platform, Standard Edition (JDK) has been removed from the official software repositories of Ubuntu and only provides a binary (.bin) version. You can get the JDK from the Java SE Downloads.

1. Check which version of the JDK your system is using:

```bash
$ java -version
```

If Oracle Java is used, the results should look like:

```text
java version "1.8.0_65"
Java(TM) SE Runtime Environment (build 1.8.0_65-b17)
Java HotSpot(TM) 64-Bit Server VM (build 25.65-b01, mixed mode)
```

2. If necessary, go to Oracle Java SE Downloads, accept the license agreement, and download the installer for your distribution.
Note: If installing the Oracle JDK in a cloud environment, accept the license agreement, download the installer to your local client, and then use `scp` (secure copy) to transfer the file to your cloud machines.

3. Make a directory for the JDK:

   $ sudo mkdir -p /usr/lib/jvm

4. Unpack the tarball and install the JDK:

   $ sudo tar zxf jdk-8u65-linux-x64.tar.gz -C /usr/lib/jvm

   The JDK files are installed into a directory called `/usr/lib/jvm/jdk-8u_version`.

5. Tell the system that there's a new Java version available:

   $ sudo update-alternatives --install "/usr/bin/java" "java" "/usr/lib/jvm/jdk1.8.0_version/bin/java" 1

   If updating from a previous version that was removed manually, you may need to execute the above command twice, because you'll get an error message the first time.

6. Set the new JDK as the default using the following command:

   $ sudo update-alternatives --config java

7. Make sure your system is using the correct JDK:

   $ java -version

   java version "1.8.0_65"
   Java(TM) SE Runtime Environment (build 1.8.0_65-b17)
   Java HotSpot(TM) 64-Bit Server VM (build 25.65-b01, mixed mode)

**Installing OpenJDK on RHEL-based systems**

Configure your operating system to use the OpenJDK 8.

In a terminal:

1. Install the OpenJDK 8:
Installing Apache Cassandra 3.0

1. To install Apache Cassandra 3.0, you can use the following command:

   $ su -c "yum install java-1.8.0-openjdk"

2. If you have more than one Java version installed on your system use the following command to switch versions:

   $ sudo alternatives --config java

3. Make sure your system is using the correct JDK:

   $ java -version

   openjdk version "1.8.0_71"
   OpenJDK Runtime Environment (build 1.8.0_71-b15)
   OpenJDK 64-Bit Server VM (build 25.71-b15, mixed mode)

Installing OpenJDK on Debian-based systems

Configure your operating system to use the OpenJDK 8.

In a terminal:

1. Install the OpenJDK 8 from a PPA repository:

   $ sudo add-apt-repository ppa:openjdk-r/ppa

2. Update the system package cache and install:

   $ sudo apt-get update
   $ sudo apt-get install openjdk-8-jdk

3. If you have more than one Java version installed on your system use the following command to switch versions:

   $ sudo update-alternatives --config java

4. Make sure your system is using the correct JDK:

   $ java -version

   openjdk version "1.8.0_72-internal"
   OpenJDK Runtime Environment (build 1.8.0_72-internal-b05)
Recommended production settings for Linux

Recommendations for production environments have been moved to Recommended production settings in the DataStax Enterprise Administrator Guide (page ).

Install locations

Tarball installation directories

The configuration files are located in the following directories:

- The binary tarball releases install into the installation directory.
- For DataStax Enterprise installs, see the documentation for your DataStax Enterprise version.

Package installation directories

The configuration files are located in the following directories:

- The packaged releases install into these directories:
- For DataStax Enterprise installs, see the documentation for your DataStax Enterprise version.
Configuration

The cassandra.yaml configuration file

The cassandra.yaml file is the main configuration file for Cassandra.

**Important:** After changing properties in the cassandra.yaml file, you must restart the node for the changes to take effect. It is located in the following directories:

- **Cassandra package installations:** /etc/cassandra
- **Cassandra tarball installations:** install_location/conf
- **DataStax Enterprise package installations:** /etc/dse/cassandra
- **DataStax Enterprise tarball installations:** install_location/resources/cassandra/conf

The configuration properties are grouped into the following sections:

- **Quick start** *(page 86)*
  
The minimal properties needed for configuring a cluster.

- **Commonly used** *(page 89)*
  
  Properties most frequently used when configuring Cassandra.

- **Performance tuning** *(page 95)*
  
  Tuning performance and system resource utilization, including commit log, compaction, memory, disk I/O, CPU, reads, and writes.

- **Advanced** *(page 99)*
  
  Properties for advanced users or properties that are less commonly used.

- **Security** *(page 111)*
  
  Server and client security settings.

**Note:** Values with *note* mark default values that are defined internally, missing, or commented out, or whose implementation depends on other properties in the cassandra.yaml file. Additionally, some commented-out values may not match the actual default values. These are recommended alternatives to the default values.

Quick start properties

The minimal properties needed for configuring a cluster.
Related information: Initializing a multiple node cluster (single datacenter) (page 168) and Initializing a multiple node cluster (multiple datacenters) (page 172).

**cluster_name**
(Default: Test Cluster) The name of the cluster. This setting prevents nodes in one logical cluster from joining another. All nodes in a cluster must have the same value.

**listen_address**
(Default: localhost) The IP address or hostname that Cassandra binds to for connecting this node to other nodes. Set this parameter or listen_interface (page 88), not both. Correct settings for various use cases:

- **Single-node installations**: do one of the following:
  - Comment this property out. If the node is properly configured (host name, name resolution, and so on.), Cassandra uses InetAddress.getLocalHost() to get the local address from the system.
  - Leave set to the default, localhost.

- **Node in a multi-node installations**: set this property to the node's IP address or hostname, or set listen_interface (page 88).

- **Node in a multi-network or multi-Datacenter installation, within an EC2 environment that supports automatic switching between public and private interfaces**: set listen_address to the node's IP address or hostname, or set listen_interface (page 88).

- **Node with two physical network interfaces in a multi-datacenter installation or a Cassandra cluster deployed across multiple Amazon EC2 regions using the Ec2MultiRegionSnitch**:
  1. Set listen_address to this node's private IP or hostname, or set listen_interface (page 88) (for communication within the local datacenter).
  2. Set broadcast_address (page 100) to the second IP or hostname (for communication between datacenters).
  3. Set listen_on_broadcast_address (page 100) to true.
  4. If this node is a seed node, add the node's public IP address or hostname to the seeds (page 92) list.

- Open the storage_port (page 102) or ssl_storage_port (page 116) on the public IP firewall.

**Warning:**

- Never set listen_address to 0.0.0.0. It is always wrong.
• Do not set values for both `listen_address` (page 87) and `listen_interface` on the same node.

`listen_interface`

(Default: `eth0`) The interface that Cassandra binds to for connecting to other Cassandra nodes. Interfaces must correspond to a single address — IP aliasing is not supported. Do not set values for both `listen_address` (page 87) and `listen_interface` on the same node.

`listen_interface_prefer_ipv6`

(Default: `false`) If an interface has an ipv4 and an ipv6 address, Cassandra uses the first ipv4 address by default. Set this property to `true` to configure Cassandra to use the first ipv6 address.

Default directories

If you have changed any of the default directories during installation, set these properties to the new locations. Make sure you have root access.

`cdc_raw_directory`

The directory where the CDC log is stored. Default locations:

- DataStax Enterprise 5.0 Installer-Services and package installations: `/var/lib/cassandra/cdc_raw`
- DataStax Enterprise 5.0 Installer-No Services and tarball installations: `/var/lib/cassandra/cdc_raw`
- Cassandra package installations: `/var/lib/cassandra/cdc_raw`
- Cassandra tarball installations: `install_location/data/cdc_raw`

The directory where Change Data Capture logs are stored.

`commitlog_directory`

The directory where the commit log is stored. Default locations:

- DataStax Enterprise 5.0 Installer-Services and package installations: `/var/lib/cassandra/commitlog`
- DataStax Enterprise 5.0 Installer-No Services and tarball installations: `/var/lib/cassandra/commitlog`
- Cassandra package installations: `/var/lib/cassandra/commitlog`
- Cassandra tarball installations: `install_location/data/commitlog`

For optimal write performance, place the commit log be on a separate disk partition, or (ideally) a separate physical device from the data file directories. Because the commit log is append only, an HDD is acceptable for this purpose.

`data_file_directories`

The directory location where table data is stored (in SSTables). Cassandra distributes data evenly across the location, subject to the granularity of the configured compaction strategy. Default locations:
• DataStax Enterprise 5.0 Installer-Services and package installations: /var/lib/cassandra/data
• DataStax Enterprise 5.0 Installer-No Services and tarball installations: /var/lib/cassandra/data
• Cassandra package installations: /var/lib/cassandra/data
• Cassandra tarball installations: install_location/data/data

As a production best practice, use RAID 0 and SSDs (page 86).

**saved_caches_directory**

The directory location where table key and row caches are stored. Default location:

• DataStax Enterprise 5.0 Installer-Services and package installations: /var/lib/cassandra/saved_caches
• DataStax Enterprise 5.0 Installer-No Services and tarball installations: /var/lib/cassandra/saved_caches
• Cassandra package installations: /var/lib/cassandra/saved_caches
• Cassandra tarball installations: install_location/data/saved_caches

Commonly used properties

Properties most frequently used when configuring Cassandra.

Before starting a node for the first time, you should carefully evaluate your requirements.

**Common initialization properties**

**Note:** Be sure to set the properties in the Quick start section (page 86) as well.

**commit_failure_policy**

(Default: stop) Policy for commit disk failures:

- **die**
  Shut down gossip and Thrift and kill the JVM, so the node can be replaced.

- **stop**
  Shut down gossip and Thrift, leaving the node effectively dead, available for inspection using JMX.

- **stop_commit**
  Shut down the commit log, letting writes collect but continuing to service reads (as in pre-2.0.5 Cassandra).

- **ignore**
  Ignore fatal errors and let the batches fail.

**disk_optimization_strategy**
Configuration

(Default: **ssd**) The strategy for optimizing disk reads. Possible values: **ssd** or **spinning**.

**disk_failure_policy**

(Default: **stop**) Sets how Cassandra responds to disk failure. Recommend settings: **stop** or **best_effort**. Valid values:

- **die**
  Shut down gossip and Thrift and kill the JVM for any file system errors or single SSTable errors, so the node can be replaced.

- **stop_paranoid**
  Shut down gossip and Thrift even for single SSTable errors.

- **stop**
  Shut down gossip and Thrift, leaving the node effectively dead, but available for inspection using JMX.

- **best_effort**
  Stop using the failed disk and respond to requests based on the remaining available SSTables. This allows obsolete data at consistency level of ONE.

- **ignore**
  Ignore fatal errors and lets the requests fail; all file system errors are logged but otherwise ignored. Cassandra acts as in versions prior to 1.2.

Related information: Handling Disk Failures In Cassandra 1.2 blog and Recovering from a single disk failure using JBOD (page 208).

**endpoint_snitch**

(Default: **org.apache.cassandra.locator.SimpleSnitch**) Set to a class that implements the **IEndpointSnitch** interface. Cassandra uses the snitch to locate nodes and route requests.

**Important:** Use only snitch implementations bundled with DSE.

- **SimpleSnitch**
  Use for single-datacenter deployment or single-zone deployment in public clouds. Does not recognize datacenter or rack information. Treats strategy order as proximity, which can improve cache locality when you disable read repair.

- **GossipingPropertyFileSnitch**
  Recommended for production. Reads rack and datacenter for the local node in cassandra-rackdc.properties file and propagates these values to other nodes via gossip. For migration from the PropertyFileSnitch, uses the cassandra-topology.properties file if it is present.
The location of the `cassandra-rackdc.properties` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-rackdc.properties</td>
</tr>
</tbody>
</table>

The location of the `cassandra-topology.properties` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-topology.properties</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-topology.properties</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-topology.properties</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-topology.properties</td>
</tr>
</tbody>
</table>

- **PropertyFileSnitch**
  
  Determines proximity by rack and datacenter, which are explicitly configured in `cassandra-topology.properties` file.

- **Ec2Snitch**
  
  For EC2 deployments in a single region. Loads region and availability zone information from the Amazon EC2 API. The region is treated as the datacenter and the availability zone as the rack and uses only private IP addresses. For this reason, it does not work across multiple regions.

- **Ec2MultiRegionSnitch**
  
  Uses the public IP as the `broadcast_address` (page 100) to allow cross-region connectivity. This means you must also set `seed` (page 92) addresses to the public IP and open the `storage_port` (page 102) or `ssl_storage_port` (page 116) on the public IP firewall. For intra-region traffic, Cassandra switches to the private IP after establishing a connection.

- **RackInferringSnitch**
Proximity is determined by rack and datacenter, which are assumed to correspond to the 3rd and 2nd octet of each node's IP address, respectively. Best used as an example for writing a custom snitch class (unless this happens to match your deployment conventions).

- **GoogleCloudSnitch:**

  Use for Cassandra deployments on Google Cloud Platform across one or more regions. The region is treated as a datacenter and the availability zones are treated as racks within the datacenter. All communication occurs over private IP addresses within the same logical network.

- **CloudstackSnitch**

  Use the CloudstackSnitch for Apache Cloudstack environments.

Related information: Snitches (page 28)

**rpc_address**
- (Default: localhost) The listen address for client connections (Thrift RPC service and native transport). Valid values:
  - **unset:**
    - Resolves the address using the configured hostname configuration of the node. If left unset, the hostname resolves to the IP address of this node using /etc/hostname, /etc/hosts, or DNS.
  - **0.0.0.0:**
    - Listens on all configured interfaces. You must set the broadcast_rpc_address (page 107) to a value other than 0.0.0.0.

- **IP address**
- **hostname**

Related information: Network (page )

**rpc_interface**
- (Default: eth1)\(^\text{note}\) (page 86) The listen address for client connections. Interface must correspond to a single address, IP aliasing is not supported. See rpc_address (page 92).

**rpc_interface_prefer_ipv6**
- (Default: false) If an interface has an ipv4 and an ipv6 address, Cassandra uses the first ipv4 address by default, i. If set to true, the first ipv6 address will be used.

**seed_provider**
- The addresses of hosts designated as contact points in the cluster. A joining node contacts one of the nodes in the -seeds list to learn the topology of the ring.

  **Important:** Use only seed provider implementations bundled with DSE.
• **class_name** (Default: org.apache.cassandra.locator.SimpleSeedProvider)

  The class within Cassandra that handles the seed logic. It can be customized, but this is typically not required.

• **seeds** (Default: 127.0.0.1)

  A comma-delimited list of IP addresses used by *gossip (page 21)* for bootstrapping new nodes joining a cluster. If your cluster includes multiple nodes, you must change the list from the default value to the IP address of one of the nodes.

  **Attention:** In multiple data-center clusters, include at least one node from each datacenter (replication group) in the seed list. Designating more than a single seed node per datacenter is recommended for fault tolerance. Otherwise, gossip has to communicate with another datacenter when bootstrapping a node.

  Making every node a seed node is **not** recommended because of increased maintenance and reduced gossip performance. Gossip optimization is not critical, but it is recommended to use a small seed list (approximately three nodes per datacenter).

  Related information: Initializing a multiple node cluster (single datacenter) *(page 168)* and Initializing a multiple node cluster (multiple datacenters) *(page 172).*

**enable_user_defined_functions**

  (Default: false) User defined functions (UDFs) present a security risk, since they are executed on the server side. In Cassandra 3.0 and later, UDFs are executed in a sandbox to contain the execution of malicious code. They are disabled by default.

**enable_scripted_user_defined_functions**

  (Default: false) Java UDFs are always enabled, if `enable_user_defined_functions` is **true**. Enable this option to use UDFs with language javascript or any custom JSR-223 provider. This option has no effect if `enable_user_defined_functions` is **false**.

**Common compaction settings**

**compaction_throughput_mb_per_sec**

  (Default: 16) Throttles compaction to the specified Mb/second across the instance. The faster Cassandra inserts data, the faster the system must compact in order to keep the SSTable count down. The recommended value is 16 to 32 times the rate of write throughput (in Mb/second). Setting the value to 0 disables compaction throttling.

  Related information: Configuring compaction *(page 241)*

**compaction_large_partition_warning_threshold_mb**
Configuration

(Default: 100) Cassandra logs a warning when compacting partitions larger than the set value.

Common memtable settings

**memtable_heap_space_in_mb**

(Default: 1/4 of heap size)\(^{\text{note}}\) (page 86)
The amount of on-heap memory allocated for memtables. Cassandra uses the total of this amount and the value of **memtable_offheap_space_in_mb** to set a threshold for automatic memtable flush. For details, see **memtable_cleanup_threshold** (page 97).

Related information: Tuning the Java heap (page 234)

**memtable_offheap_space_in_mb**

(Default: 1/4 of heap size)\(^{\text{note}}\) (page 86)
Sets the total amount of off-heap memory allocated for memtables. Cassandra uses the total of this amount and the value of **memtable_heap_space_in_mb** to set a threshold for automatic memtable flush. For details, see **memtable_cleanup_threshold** (page 97).

Related information: Tuning the Java heap (page 234)

Common disk settings

**concurrent_reads**

(Default: 32)\(^{\text{note}}\) (page 86) Workloads with more data than can fit in memory encounter a bottleneck in fetching data from disk during reads. Setting **concurrent_reads** to \((16 \times \text{number\_of\_drives})\) allows operations to queue low enough in the stack so that the OS and drives can reorder them. The default setting applies to both logical volume managed (LVM) and RAID drives.

**concurrent_writes**

(Default: 32)\(^{\text{note}}\) (page 86) Writes in Cassandra are rarely I/O bound, so the ideal number of concurrent writes depends on the number of CPU cores on the node. The recommended value is \(8 \times \text{number\_of\_cpu\_cores}\).

**concurrent_counter_writes**

(Default: 32)\(^{\text{note}}\) (page 86) Counter writes read the current values before incrementing and writing them back. The recommended value is \((16 \times \text{number\_of\_drives})\).

**concurrent_batchlog_writes**

(Default: 32) Limit on the number of concurrent batchlog writes, similar to **concurrent_writes**.

**concurrent_materialized_view_writes**

(Default: 32) Limit on the number of concurrent materialized view writes. Set this to the lesser of concurrent reads or concurrent writes, because there is a read involved in each materialized view write.
**Common automatic backup settings**

**incremental_backups**  
(Default: **false**) Backs up data updated since the last snapshot was taken. When enabled, Cassandra creates a hard link to each SSTable flushed or streamed locally in a backups subdirectory of the keyspace data. Removing these links is the operator's responsibility.

Related information: Enabling incremental backups *(page 204)*

**snapshot_before_compaction**  
(Default: **false**) Enables or disables taking a snapshot before each compaction. A snapshot is useful to back up data when there is a data format change. Be careful using this option: Cassandra does not clean up older snapshots automatically.

Related information: Configuring compaction *(page 241)*

**Common fault detection setting**

**phi_convict_threshold**  
(Default: **8**)*note* *(page 86)* Adjusts the sensitivity of the failure detector on an exponential scale. Generally this setting does not need adjusting.

Related information: Failure detection and recovery *(page 21)*

**Performance tuning properties**

Tuning performance and system resource utilization, including commit log, compaction, memory, disk I/O, CPU, reads, and writes.

**Commit log settings**

**commitlog_sync**  
(Default: **periodic**) The method that Cassandra uses to acknowledge writes in milliseconds:

- **periodic**: (Default: **10000** milliseconds [10 seconds])

  With commitlog_sync_period_in_ms, controls how often the commit log is synchronized to disk. Periodic syncs are acknowledged immediately.

- **batch**: (Default: **disabled**)*note* *(page 86)*

  Used with commitlog_sync_batch_window_in_ms (Default: 2 ms), which is the maximum length of time that queries may be batched together.

**commitlog_segment_size_in_mb**  
(Default: **32**MB) The size of an individual commitlog file segment. A commitlog segment may be archived, deleted, or recycled after all its data has been flushed to SSTables. This data can potentially include commitlog segments from every table in the system. The default size is usually suitable for most commitlog archiving, but if you want a finer granularity, 8 or 16 MB is reasonable.
By default, the `max_mutation_size_in_kb (page 96)` is set to half of the `commitlog_segment_size_in_kb`.

Related information: Commit log archive configuration (page 163)

**max_mutation_size_in_kb**
(Default: ½ of `commitlog_segment_size_in_mb (page 95)`.

If a mutation's size exceeds this value, the mutation is rejected. Before increasing the commitlog segment size of the commitlog segments, investigate why the mutations are larger than expected. Look for underlying issues with access patterns and data model, because increasing the commitlog segment size is a limited fix.

Restriction:

If you set `max_mutation_size_in_kb` explicitly, then you must set `commitlog_segment_size_in_mb` to at least twice the size of `max_mutation_size_in_kb / 1024`.

For more information, see `commitlog_segment_size_in_mb (page 95)` above.

**commitlog_compression**
(Default: not enabled) The compressor to use if commit log is compressed. Valid values: LZ4, Snappy or Deflate. If no value is set for this property, the commit log is written uncompressed.

**cdc_total_space_in_mb**
(Default: 4096MB and 1/8th of the total space of the drive where the cdc_raw_directory resides.)

If space gets above this value, Cassandra will throw `WriteTimeoutException` on Mutations including tables with CDC enabled. A CDCCompactor (a consumer) is responsible for parsing the raw CDC logs and deleting them when parsing is completed.

**cdc_free_space_check_interval_ms**
(Default: 250 ms)

When the cdc_raw limit is hit and the CDCCompactor is either running behind or experiencing backpressure, this interval is checked to see if any new space for cdc-tracked tables has been made available.

**commitlog_total_space_in_mb**
(Default: 32MB for 32-bit JVMs, 8192MB for 64-bit JVMs)

Total space used for commit logs. If the total space used by all commit logs goes above this value, Cassandra rounds up to the next nearest segment multiple and flushes memtables to disk for the oldest commitlog segments, removing those log segments from the commit log. This reduces the amount of data to replay on start-up, and prevents infrequently-updated tables from keeping commitlog segments indefinitely. If the `commitlog_total_space_in_mb` is small, the result is more flush activity on less-active tables.

Related information: Configuring memtable thresholds (page 241)
**Compaction settings**

Related information: Configuring compaction (page 241)

**concurrent_compactors**

(Default: Smaller of number of disks or number of cores, with a minimum of 2 and a maximum of 8 per CPU core)\(^\text{note}\) (page 86) The number of concurrent compaction processes allowed to run simultaneously on a node, not including validation compactions (page ) for anti-entropy (page ) repair. Simultaneous compactions help preserve read performance in a mixed read-write workload by limiting the number of small SSTables that accumulate during a single long-running compaction. If your data directories are backed by SSDs (page ), increase this value to the number of cores. If compaction running too slowly or too fast, adjust compaction_throughput_mb_per_sec (page 93) first.

**Note:** Increasing concurrent compactors leads to more use of available disk space for compaction, because concurrent compactions happen in parallel, especially for STCS. Ensure that adequate disk space is available before increasing this configuration.

**sstable_preemptive_open_interval_in_mb**

(Default: 50MB) The compaction process opens SSTables before they are completely written and uses them in place of the prior SSTables for any range previously written. This setting helps to smoothly transfer reads between the SSTables by reducing page cache churn and keeps hot rows hot.

**Memtable settings**

**memtable_allocation_type**

(Default: heap_buffers) The method Cassandra uses to allocate and manage memtable memory. See Off-heap memtables in Cassandra 2.1. In releases 3.2.0 and 3.2.1, the only option that works is: heap-buffers (On heap NIO (non-blocking I/O) buffers).

**memtable_cleanup_threshold**

(Default: 1/(memtable_flush_writers (page 98) + 1))\(^\text{note}\) (page 86). Ratio used for automatic memtable flush. Cassandra adds memtable_heap_space_in_mb (page 94) to memtable_offheap_space_in_mb (page 94) and multiplies the total by memtable_cleanup_threshold to get a space amount in MB. When the total amount of memory used by all non-flushing memtables exceeds this amount, Cassandra flushes the largest memtable to disk.

For example, consider a node where the total of memtable_heap_space_in_mb and memtable_offheap_space_in_mb is 1000, and memtable_cleanup_threshold is 0.50. The memtable_cleanup amount is 500MB. This node has two memtables: Memtable A (150MB) and Memtable B (350MB). When either memtable increases, the total space they use exceeds 500MB and Cassandra flushes the Memtable B to disk.
A larger value for `memtable_cleanup_threshold` means larger flushes, less frequent flushes and potentially less compaction activity, but also less concurrent flush activity, which can make it difficult to keep your disks saturated under heavy write load.

This section documents the formula used to calculate the ratio based on the number of `memtable_flush_writers` (page 98). The default value in `cassandra.yaml` is 0.11, which works if the node has many disks or if you set the node’s `memtable_flush_writers` to 8. As another example, if the node uses a single SSD, the value for `memtable_cleanup_threshold` computes to 0.33, based on the minimum `memtable_flush_writers` value of 2.

**file_cache_size_in_mb**
(_Default: Smaller of 1/4 heap or 512) Total memory to use for SSTable-reading buffers.

**buffer_pool_use_heap_if_exhausted**
(_Default: true)\(^{\text{note} \ (page \ 86)}\) Indicates whether Cassandra allocates allocate on-heap or off-heap memory when the SSTable buffer pool is exhausted (when the buffer pool has exceeded the maximum memory `file_cache_size_in_mb` (page 98)), beyond this amount, Cassandra stops caching buffers, but allocates on request.

**memtable_flush_writers**
(_Default: Smaller of number of disks or number of cores with a minimum of 2 and a maximum of 8)\(^{\text{note} \ (page \ 86)}\) The number of memtable flush writer threads. These threads are blocked by disk I/O, and each one holds a memtable in memory while blocked. If your data directories are backed by SSDs, increase this setting to the number of cores.

**Cache and index settings**

**column_index_size_in_kb**
(_Default: 64) Granularity of the index of rows within a partition. For huge rows, decrease this setting to improve seek time. If you use key cache, be careful not to make this setting too large because key cache will be overwhelmed. If you’re unsure of the size of the rows, it’s best to use the default setting.

**index_summary_capacity_in_mb**
(_Default: 5% of the heap size \[empty\])\(^{\text{note} \ (page \ 86)}\) Fixed memory pool size in MB for SSTable index summaries. If the memory usage of all index summaries exceeds this limit, any SSTables with low read rates shrink their index summaries to meet this limit. This is a best-effort process. In extreme conditions, Cassandra may use more than this amount of memory.

**index_summary_resize_interval_in_minutes**
(_Default: 60 minutes) How frequently index summaries should be re-sampled. Re-sampling is done periodically to redistribute memory from the fixed-size pool to SSTables proportional their recent read rates. To disable, set to -1. This setting leaves existing index summaries at their current sampling level.
Disks settings

stream_throughput_outbound_megabits_per_sec
(_Default: 200 Mbps)\textsuperscript{note} (page 86) Throttle for the throughput of all outbound streaming file transfers on a node. Cassandra does mostly sequential I/O when streaming data during bootstrap or repair. This can saturate the network connection and degrade client (RPC) performance.

inter_dc_stream_throughput_outbound_megabits_per_sec
(_Default: unset)\textsuperscript{note} (page 86) Throttle for all streaming file transfers between datacenters, and for network stream traffic as configured with stream_throughput_outbound_megabits_per_sec (page 99).

trickle_fsync
(_Default: false) When set to true, causes fsync to force the operating system to flush the dirty buffers at the set interval trickle_fsync_interval_in_kb. Enable this parameter to prevent sudden dirty buffer flushing from impacting read latencies. Recommended for use with SSDs, but not with HDDs.

trickle_fsync_interval_in_kb
(_Default: \texttt{10240}). The size of the fsync in kilobytes.

Advanced properties

Properties for advanced users or properties that are less commonly used.

Advanced initialization properties

auto_bootstrap
(_Default: true) This setting has been removed from default configuration. It causes new (non-seed) nodes migrate the right data to themselves automatically. When initializing a fresh cluster without data, add auto_bootstrap: false.

Related information: Initializing a multiple node cluster (single datacenter) (page 168) and Initializing a multiple node cluster (multiple datacenters) (page 172).

batch_size_warn_threshold_in_kb
(_Default: 5KB per batch) Causes Cassandra to log a WARN message when any batch size exceeds this value in kilobytes.

\textbf{Caution}: Increasing this threshold can lead to node instability.

batch_size_fail_threshold_in_kb
(_Default: 50KB per batch) Cassandra fails any batch whose size exceeds this setting. The default value is 10X the value of batch_size_warn_threshold_in_kb.

unlogged_batch_across_partitions_warn_threshold
(_Default: 10partitions per batch) Causes Cassandra to log a WARN message on any batches not of type LOGGED that span across more partitions than this limit. The default value is 10 partitions.

cdc_enabled
**Configuration**

(Default: **commented out**) Enable / disable CDC functionality on a per-node basis. This modifies the logic used for write path allocation rejection (standard: never reject. cdc: reject Mutation containing a CDC-enabled table if at space limit in cdc_raw_directory).

**Important:** Do not enable CDC on a mixed-version cluster. Upgrade all nodes to Cassandra 3.8 before enabling and restarting the cluster.

**broadcast_address**

(Default: **listen_address**)[note](page 86) The "public" IP address this node uses to broadcast to other nodes outside the network or across regions in multiple-region EC2 deployments. If this property is commented out, the node uses the same IP address or hostname as **listen_address**. A node does not need a separate **broadcast_address** in a single-node or single-datacenter installation, or in an EC2-based network that supports automatic switching between private and public communication. It is necessary to set a separate **listen_address** and **broadcast_address** on a node with multiple physical network interfaces or other topologies where not all nodes have access to other nodes by their private IP addresses. For specific configurations, see the instructions for **listen_address**.(page 87).

**listen_on_broadcast_address**

(Default: **false**) If this node uses multiple physical network interfaces, set a unique IP address for **broadcast_address**(page 100) and set **listen_on_broadcast_address** to **true**. This enables the node to communicate on both interfaces.

Set this property to **false** if the node is on a network that automatically routes between public and private networks, as Amazon EC2 does.

For configuration details, see the instructions for **listen_address**(page 87).

**initial_token**

(Default: **disabled**) Set this property for single-node-per-token architecture, in which a node owns exactly one contiguous range in the ring space. Setting this property overrides **num_tokens**(page 100).

If your Cassandra installation is not using vnodes or this node's **num_tokens**(page 100) is set it to 1 or is commented out, you should always set an **initial_token** value when setting up a production cluster for the first time, and when adding capacity. For more information, see this parameter in the Cassandra 1.1 Node and Cluster Configuration (page ) documentation.

This parameter can be used with **num_tokens** (vnodes ) in special cases such as Restoring from a snapshot (page 205).

**Note:**

If you are using DataStax Enterprise, your node's setting for this property depends on the type of node and type of install. For more information, see Virtual node (vnode) configuration (page ).

**num_tokens**
Configuration

(Defaul: 1 disabled) Set this property for virtual node token architecture. Determines the number of token ranges to assign to this (vnode). Use a number between 1 and 256, where 1 disables vnodes. When the token number varies between nodes in a datacenter, the vnode logic assigns a proportional number of ranges relative to other nodes in the datacenter. In general, if all nodes have equal hardware capability, each node should have the same num_tokens value.

- **Random selection algorithm**: Assign token ranges randomly. A higher num_token value increases the probability that the data and workload are evenly distributed. For recommended settings when randomly assigning token ranges, see Virtual node (vnode) configuration (page ).
- **Allocation algorithm**: Assign token ranges using the allocation algorithm which optimizes the workload balance using the target keyspace replication factor. Enabled when the allocate_tokens_for_local_replication_factor (page 101) is set. DataStax recommends setting the number of tokens to 8 to distribute the workload with ~10% variance between nodes.

To migrate an existing cluster from single node per token range to vnodes, see Enabling virtual nodes on an existing production cluster (page 155). Note: All other nodes in the datacenter must have the same token architecture, that is single-token, random algorithm vnode or allocation algorithm vnode architecture.

allocate_tokens_for_local_replication_factor

When adding a vnode to an existing cluster or setting up nodes in a new datacenter, set to the target replication factor (RF) of keyspaces in the datacenter. Triggers algorithmic allocation for the RF and num_tokens for this node. The allocation algorithm attempts to choose tokens in a way that optimizes replicated load over the nodes in the datacenter for the specified RF. The load assigned to each node is close to proportional to the number of vnodes.

For an explanation of the random and allocation algorithms, see Virtual node (vnode) configuration (page ). For set up instructions, see Adding nodes to an existing cluster (page 178) or Adding a datacenter to a cluster (page 180).

Note: The allocation algorithm is supported only for the Murmur3Partitioner and RandomPartitioner partitioners.

allocate_tokens_for_keyspace (deprecated)

(Defaul: KEYSPACE) REPLACED BY allocate_tokens_for_local_replication_factor. Enables automatic allocation of num_tokens tokens for this node. The allocation algorithm attempts to choose tokens in a way that optimizes replicated load over the nodes in the datacenter for the replication strategy used by the specified KEYSPACE. The load assigned to each node will near proportional to its number of vnodes.

partitioner

(Defaul: org.apache.cassandra.dht.Murmur3Partitioner) Sets the class that distributes rows (by partition key) across all nodes in the cluster. Any IPartitioner
Configuration

may be used, including your own as long as it is in the class path. For new clusters use the default partitioner.

Cassandra provides the following partitioners for backwards compatibility:

- RandomPartitioner
- ByteOrderedPartitioner (deprecated)
- OrderPreservingPartitioner (deprecated)

Important: Use only partitioner implementations bundled with DSE.

Related information: Partitioners (page 26)

storage_port
(Default: 7000) The port for inter-node communication.

tracetype_query_ttl
(Default: 86400) TTL for different trace types used during logging of the query process

tracetype_repair_ttl
(Default: 604800) TTL for different trace types used during logging of the repair process.

Advanced automatic backup setting

auto_snapshot
(Default: true) Whether Cassandra takes a snapshot of the data before truncating a keyspace or dropping a table. To prevent data loss, DataStax strongly advises using the default setting. If you set auto_snapshot to false, data loss occurs on truncation or drop.

Key caches and global row properties

When creating or modifying tables, you can enable or disable the key cache (partition key cache) or row cache for that table by setting the caching parameter. Other row and key cache tuning and configuration options are set at the global (node) level. Cassandra uses these settings to automatically distribute memory for each table on the node based on the overall workload and specific table usage. You can also configure the save periods for these caches globally.

Related information: Configuring caches (page 237)

key_cache_keys_to_save
(Default: disabled - all keys are saved) Note (page 86) Number of keys from the key cache to save.

key_cache_save_period
(Default: 14400 seconds [4 hours]) Duration in seconds that keys are kept in cache. Caches are saved to saved_caches_directory (page 89). Saved caches greatly improve cold-start speeds and have relatively little effect on I/O.

key_cache_size_in_mb
(Default: empty) A global cache setting for the maximum size of the key cache in memory (for all tables). If no value is set, the cache is set to the smaller of 5% of the available heap, or 100MB. To disable set to 0.

Related information: nodetool setcachecapacity (page 322), Enabling and configuring caching (page 238).

column_index_cache_size_in_kb
(Defaul: 2) A threshold for the total size of all index entries for a partition that Cassandra stores in the partition key cache. If the total size of all index entries for a partition exceeds this amount, Cassandra stops putting entries for this partition into the partition key cache. This limitation prevents index entries from large partitions from taking up all the space in the partition key cache (which is controlled by key_cache_size_in_mb).

row_cache_class_name
(Defaul: disabled - row cache is not enabled) note (page 86) The classname of the row cache provider to use. Valid values: OHCProvider (fully off-heap) or SerializingCacheProvider (partially off-heap).

Important: Use only row cache provider implementations bundled with DSE.

row_cache_keys_to_save
(Defaul: disabled - all keys are saved) note (page 86) Number of keys from the row cache to save.

row_cache_size_in_mb
(Defaul: 0- disabled) Maximum size of the row cache in memory. The row cache can save more time than key_cache_size_in_mb (page 102), but it is space-intensive because it contains the entire row. Use the row cache only for hot rows or static rows. If you reduce the size, you may not get you hottest keys loaded on start up.

row_cache_save_period
(Defaul: 0- disabled) The number of seconds that rows are kept in cache. Caches are saved to saved_caches_directory (page 89). This setting has limited use as described in row_cache_size_in_mb.

Counter caches properties

Counter cache helps to reduce counter locks' contention for hot counter cells. In case of RF = 1 a counter cache hit causes Cassandra to skip the read before write entirely. With RF > 1 a counter cache hit still helps to reduce the duration of the lock hold, helping with hot counter cell updates, but does not allow skipping the read entirely. Only the local (clock, count) tuple of a counter cell is kept in memory, not the whole counter, so it is relatively cheap.

Note: If you reduce the counter cache size, Cassandra may load the hottest keys start-up.

counter_cache_size_in_mb
(Defaul value: empty) note (page 86) When no value is set, Cassandra uses the smaller of minimum of 2.5% of Heap or 50MB. If your system performs counter
Configuration

deletes and relies on low gc_grace_seconds (page ), you should disable the
counter cache. To disable, set to 0.

counter_cache_save_period
(DefaultValue: 7200 seconds [2 hours]) the amount of time after which Cassandra saves
the counter cache (keys only). Cassandra saves caches to saved_caches_directory
(page 89).

counter_cache_keys_to_save
(DefaultValue: disabled)\textsuperscript{note} (page 86) Number of keys from the counter cache
to save. When this property is disabled, Cassandra saves all keys.

Tombstone settings

When executing a scan, within or across a partition, Cassandra must keep tombstones in
memory to allow them to return to the coordinator. The coordinator uses tombstones to
ensure that other replicas know about the deleted rows. Workloads that generate numerous
tombstones may cause performance problems and exhaust the server heap. See Cassandra
anti-patterns: Queues and queue-like datasets. Adjust these thresholds only if you understand
the impact and want to scan more tombstones. You can adjust these thresholds at runtime
using the StorageServiceMBean.

Related information: Cassandra anti-patterns: Queues and queue-like datasets

tombstone_warn_threshold
(DefaultValue: 1000) Cassandra issues a warning if a query scans more than this number
of tombstones.

tombstone_failure_threshold
(DefaultValue: 100000) Cassandra aborts a query if it scans more than this number of
tombstones.

Network timeout settings

range_request_timeout_in_ms
(DefaultValue: 10000 milliseconds) The number of milliseconds that the coordinator waits
for sequential or index scans to complete before timing it out.

read_request_timeout_in_ms
(DefaultValue: 5000 milliseconds) The number of milliseconds that the coordinator waits
for read operations to complete before timing it out.

counter_write_request_timeout_in_ms
(DefaultValue: 5000 milliseconds) The number of milliseconds that the coordinator waits
for counter writes to complete before timing it out.

cas_contention_timeout_in_ms
(DefaultValue: 1000 milliseconds) The number of milliseconds during which the
coordinator continues to retry a CAS (compare and set) operation that contends with
other proposals for the same row. If the coordinator cannot complete the operation
within this timespan, it aborts the operation.

truncate_request_timeout_in_ms
Configuration

(Default: **60000** milliseconds) The number of milliseconds that the coordinator waits for a truncate (the removal of all data from a table) to complete before timing it out. The long default value allows Cassandra to take a snapshot before removing the data. If `auto_snapshot` (page 102) is disabled (not recommended), you can reduce this time.

**write_request_timeout_in_ms**
Default: 2000. The number of milliseconds that the coordinator waits for a write operations to complete before timing it out for requests with at least one node in the local datacenter.

Related information: Hinted Handoff: repair during write path (page 213)

**cross_dc_rtt_in_ms**
Default: 0. Increases the cross-datacenter timeout (`write_request_timeout_in_ms` + `cross_dc_rtt_in_ms`) for requests that only involve nodes in a remote datacenter. This setting is intended to reduce hint pressure.

**Tip:** DataStax recommends using `LOCAL_*` consistency levels (CL) for read and write requests in multi-datacenter deployments to avoid timeouts that may occur when remote nodes are chosen to satisfy the CL, such as `QUORUM`.

**request_timeout_in_ms**
(Default: **10000** milliseconds) The default timeout value for other miscellaneous operations.

Related information: Hinted Handoff: repair during write path (page 213)

**Inter-node settings**

**cross_node_timeout**
(Default: `false`) Enables or disables operation timeout information exchange between nodes (to accurately measure request timeouts). If this property is disabled, the replica assumes any requests are forwarded to it instantly by the coordinator. During overload conditions this means extra time is required for processing already-timed-out requests.

**Caution:** Before enabling this property make sure NTP (network time protocol) is installed and the times are synchronized among the nodes.

**internode_send_buff_size_in_bytes**
(Defaut: N/A) **Note** (page 86) The sending socket buffer size in bytes for inter-node calls.

The buffer size set by this parameter and `internode_recv_buff_size_in_bytes` (page 106) is limited by `net.core.wmem_max`. If this property is not set, `net.ipv4.tcp_wmem` determines the buffer size. See man tcp and:

- `/proc/sys/net/core/wmem_max`
- `/proc/sys/net/core/rmem_max`
- `/proc/sys/net/ipv4/tcp_wmem`
- `/proc/sys/net/ipv4/tcp_wmem`
Related information: TCP settings (page 86)

**internode_recv_buff_size_in_bytes**
(Default: N/A) \(^{\text{note (page 86)}}\)
The receiving socket buffer size in bytes for internode calls.

**internode_compression**
(Default: all) Controls whether traffic between nodes is compressed. Valid values:
- **all**
  Compresses all traffic.
- **dc**
  Compresses traffic between datacenters only.
- **none**
  No compression.

**inter_dc_tcp_nodelay**
(Default: false) Enable this property or disable tcp_nodelay for inter-datacenter communication. If this property is disabled, the network sends larger, but fewer, network packets. This reduces overhead from the TCP protocol itself. However, disabling inter_dc_tcp_nodelay may increase latency by blocking cross datacenter responses.

**streaming_socket_timeout_in_ms**
(Default: 3600000 - 1 hour) \(^{\text{note (page 86)}}\) Enables or disables socket timeout for streaming operations. If a streaming times out by exceeding this number of milliseconds, Cassandra retries it from the start of the current file. Setting this value too low can result in a significant amount of data re-streaming.

*Native transport (CQL Binary Protocol)*

**start_native_transport**
(Default: true) Enables or disables the native transport server. This server uses the same address as the rpc_address (page 92), but the port it uses is different from rpc_port (page 107). See native_transport_port (page 106).

**native_transport_port**
(Default: 9042) The port where the CQL native transport listens for clients.

**native_transport_max_threads**
(Default: 128) \(^{\text{note (page 86)}}\) The maximum number of thread handling requests. Similar to rpc_max_threads (page 107), but this property differs as follows:
- The default for native_transport_max_threads is **128**; the default for rpc_max_threads is **unlimited**.
- There is no corresponding native_transport_min_threads.
• Cassandra stops idle native transport threads after 30 seconds.

**native_transport_max_frame_size_in_mb**  
(Default: **256MB**) The maximum allowed size of a frame. Frame (requests) larger than this are rejected as invalid.

**native_transport_max_concurrent_connections**  
(Default: **-1**) The maximum number of concurrent client connections. The default value of **-1** means unlimited.

**native_transport_max_concurrent_connections_per_ip**  
(Default: **-1**) The maximum number of concurrent client connections per source IP address. The default value of **-1** means unlimited.

**RPC (remote procedure call) settings**

Settings for configuring and tuning client connections.

**broadcast_rpc_address**  
(Default: unset)\(^\text{note}\)\(^{(page 86)}\) The RPC address for broadcast to drivers and other Cassandra nodes. This cannot be set to **0.0.0.0**. If left blank, Cassandra uses the **rpc_address**\(^{(page 92)}\) or **rpc_interface**\(^{(page 107)}\). If **rpc_address** or **rpc_interface** is set to **0.0.0.0**, this property must be set.

**rpc_port**  
(Default: **9160**) Thrift port for client connections.

**start_rpc**  
(Default: **true**) Enables or disables the Thrift RPC server.

**rpc_keepalive**  
(Default: **true**) Enables or disables keepalive on client connections (RPC or native).

**rpc_max_threads**  
(Default: **unlimited**\(^\text{note}\)\(^{(page 86)}\)) Regardless of your choice of RPC server (\( rpc_server_type \)\(^{(page 108)}\)), **rpc_max_threads** dictates the maximum number of concurrent requests in the RPC thread pool. If you are using the parameter sync (see \( rpc_server_type \)\(^{(page 108)}\)) it also dictates the number of clients that can be connected. A high number of client connections could cause excessive memory usage for the thread stack. Connection pooling on the client side is highly recommended. Setting a **rpc_max_threads** acts as a safeguard against misbehaving clients. If the number of threads reaches the maximum, Cassandra blocks additional connections until a client disconnects.

**rpc_min_threads**  
(Default: **16**\(^\text{note}\)\(^{(page 86)}\)) The minimum thread pool size for remote procedure calls.

**rpc_recv_buff_size_in_bytes**  
(Default: N/A)\(^\text{note}\)\(^{(page 86)}\) The receiving socket buffer size for remote procedure calls.

**rpc_send_buff_size_in_bytes**
Configuration

( Default: N/A)\textsuperscript{note} (page 86) The sending socket buffer size in bytes for remote procedure calls.

**rpc_server_type**

( Default: sync) Cassandra provides three options for the RPC server. \textit{sync} and \textit{hsha} performance is about the same, but \textit{hsha} uses less memory.

- **sync:** (Default: one thread per Thrift connection.)
  
  For a very large number of clients, memory is the limiting factor. On a 64-bit JVM, 180KB is the minimum stack size per thread and corresponds to your use of virtual memory. Physical memory may be limited depending on use of stack space.

- **hsha:**
  
  Half synchronous, half asynchronous. All Thrift clients are handled asynchronously using a small number of threads that does not vary with the number of clients. This mechanism scales well to many clients. The RPC requests are synchronous (one thread per active request).

  \textbf{Note:} If you select this option, you must change the default value (unlimited) of `rpc_max_threads (page 107).`

- Your own RPC server
  
  You must provide a fully-qualified class name of an \texttt{org.apache.cassandra.tserver.TServerFactory} that can create a server instance.

\textit{Advanced fault detection settings}

Settings to handle poorly performing or failing components.

**gc_warn_threshold_in_ms**

( Default: 1000) Any GC pause longer than this interval is logged at the WARN level. (By default, Cassandra logs any GC pause greater than 200 ms at the INFO level.)

Additional information: Configuring logging (page 160).

**max_value_size_in_mb**

Default: 256. \textsuperscript{note} (page 86) The maximum size of any value in SSTables.

It detects SSTable corruption and marks the SSTables as corrupted when the threshold is exceeded.

**dynamic_snitch_badness_threshold**

( Default: 0.1) The performance threshold for dynamically routing client requests away from a poorly performing node. Specifically, it controls how much worse a poorly performing node has to be before the \textit{dynamic snitch} (page 29) prefers other replicas over it. A value of 0.2 means Cassandra continues to prefer the static snitch values until the node response time is 20% worse than the best performing node. Until the threshold is reached, incoming requests are statically routed to the closest replica (as determined by the snitch). A value greater than zero for this parameter,
with a value of less than 1.0 for \texttt{read\_repair\_chance (page )}, maximizes cache capacity across the nodes.

**dynamic\_snitch\_reset\_interval\_in\_ms**

(Default: 600000 milliseconds) Time interval after which Cassandra resets all node scores. This allows a bad node to recover.

**dynamic\_snitch\_update\_interval\_in\_ms**

(Default: 100 milliseconds) The number of milliseconds between Cassandra’s calculation of node scores. Because score calculation is CPU intensive, be careful when reducing this interval.

**hints\_flush\_period\_in\_ms**

(Default: 10000) The number of milliseconds Cassandra waits before flushing hints from internal buffers to disk.

**hints\_directory**

(Default: \$CASSANDRA\_HOME/data/hints) The directory in which hints are stored.

**hinted\_handoff\_enabled**

(Default: true) Enables or disables hinted handoff. To enable per datacenter, add a list of datacenters. For example: hinted\_handoff\_enabled: DC1,DC2. A hint indicates that the write needs to be replayed to an unavailable node. Cassandra writes the hint to a hints file on the coordinator node.

Related information: Hinted Handoff: repair during write path (page 213)

**hinted\_handoff\_disabled\_datacenters**

(Default: none) A blacklist of datacenters that will not perform hinted handoffs. To disable hinted handoff on a certain datacenter, add its name to this list. For example: hinted\_handoff\_disabled\_datacenters: - DC1 - DC2.

Related information: Hinted Handoff: repair during write path (page 213)

**hinted\_handoff\_throttle\_in\_kb**

(Default: 1024) Maximum amount of traffic per delivery thread in kilobytes per second. This rate reduces proportionally to the number of nodes in the cluster. For example, if there are two nodes in the cluster, each delivery thread uses the maximum rate. If there are three, each node throttles to half of the maximum, since the two nodes are expected to deliver hints simultaneously.

Note: When applying this limit, Cassandra computes the hint transmission rate based on the uncompressed hint size, even if internode\_compression (page 106) or hints\_compression (page 110) is enabled.

**max\_hint\_window\_in\_ms**

(Default: 10800000 milliseconds [3 hours]) Maximum amount of time during which Cassandra generates hints for an unresponsive node. After this interval, Cassandra does not generate any new hints for the node until it is back up and responsive. If the node goes down again, Cassandra starts a new interval. This setting can prevent a sudden demand for resources when a node is brought back online and the rest of the cluster attempts to replay a large volume of hinted writes.
Related information: Failure detection and recovery (page 21)

**max_hints_delivery_threads**
(Default: 2) Number of threads Cassandra uses to deliver hints. In multiple data-center deployments, consider increasing this number because cross data-center handoff is generally slower.

**max_hints_file_size_in_mb**
(Default: 128) The maximum size for a single hints file, in megabytes.

**hints_compression**
(Default: LZ4Compressor) The compressor for hint files. Supported compressors: LZ, Snappy, and Deflate. If you do not specify a compressor, Cassandra does not compress hints files.

**batchlog_replay_throttle_in_kb**
(Default: 1024KB per second) Total maximum throttle for replaying hints. Throttling is reduced proportionally to the number of nodes in the cluster.

Request scheduler properties

Settings to handle incoming client requests according to a defined policy. If your nodes are overloaded and dropping requests, DataStax recommends that you add more nodes rather than use these properties to prioritize requests.

**request_scheduler**
(Default: org.apache.cassandra.scheduler.NoScheduler) The scheduler to handle incoming client requests according to a defined policy. This scheduler is useful for throttling client requests in single clusters containing multiple keyspaces. This parameter is specifically for requests from the client and does not affect inter-node communication. Valid values:

- org.apache.cassandra.scheduler.NoScheduler
  Cassandra does no scheduling.

- org.apache.cassandra.scheduler.RoundRobinScheduler
  Cassandra uses a round robin of client requests to a node with a separate queue for each request_scheduler_id (page 110) property.

- Cassandra uses a Java class that implements the RequestScheduler interface.

**request_scheduler_id**
(Default: keyspace) (note (page 86) The scope of the scheduler’s activity. Currently the only valid value is keyspace. See weights (page 111).

**request_scheduler_options**
(Default: disabled) A list of properties that define configuration options for request_scheduler (page 110):
• **throttle_limit**: The number of in-flight requests per client. Requests beyond this limit are queued up until running requests complete. Recommended value is 
\((\text{concurrent}\_\text{reads} + \text{concurrent}\_\text{writes}) \times 2\).

• **default_weight**: (Default: 1) \(\text{note (page 86)}\)
  How many requests the scheduler handles during each turn of the RoundRobin.

• **weights**: (Default: Keyspace: 1)
  A list of keyspaces. How many requests the scheduler handles during each turn of the RoundRobin, based on the request_scheduler_id (page 110).

**Thrift interface properties**

Legacy API for older clients. CQL (page ) is a simpler and better API for Cassandra.

**thrift_framed_transport_size_in_mb**
  (Default: 15) Frame size (maximum field length) for Thrift. The frame is the row or part of the row that the application is inserting.

**thrift_max_message_length_in_mb**
  (Default: 16) The maximum length of a Thrift message in megabytes, including all fields and internal Thrift overhead (1 byte of overhead for each frame). Calculate message length in conjunction with batches. A frame length greater than or equal to 24 accommodates a batch with four inserts, each of which is 24 bytes. The required message length is greater than or equal to 24+24+24+24+4 (number of frames).

**Security properties**

Server and client security settings.

**authenticator**
  (Default: AllowAllAuthenticator) The authentication backend. It implements IAuthenticator for identifying users. Available authenticators:

  • **AllowAllAuthenticator**:
    Disables authentication; Cassandra performs no checks.

  • **PasswordAuthenticator**
    Authenticates users with user names and hashed passwords stored in the system_auth.roles table. Leaving the default replication factor of 1 set for the system_auth keyspace results in denial of access to the cluster if the single replica of the keyspace goes down. For multiple datacenters, be sure to set the replication class to NetworkTopologyStrategy.

  **Important**: Use only authentication implementations bundled with DSE.

  Related information: About Internal authentication (page 118)
internode_authenticator

( Default: enabled)\textsuperscript{note} (page 86) Internode authentication backend. It implements org.apache.cassandra.auth.AllowAllInternodeAuthenticator to allow or disallow connections from peer nodes.

**Important:** Use only authentication implementations bundled with DSE.

**authorizer**

( Default: AllowAllAuthorizer) The authorization backend. It implements IAuthenticator to limit access and provide permissions. Available authorizers:

- AllowAllAuthorizer

  Disables authorization: Cassandra allows any action to any user.

- CassandraAuthorizer

  Stores permissions in system\_auth.permissions table. Leaving the default replication factor of 1 set for the system\_auth keyspace results in denial of access to the cluster if the single replica of the keyspace goes down. For multiple datacenters, be sure to set the replication class to NetworkTopologyStrategy.

**Important:** Use only authorization implementations bundled with DSE.

**Related information:** Object permissions (page 124)

**role_manager**

( Default: CassandraRoleManager) Part of the Authentication & Authorization backend that implements IRoleManager to maintain grants and memberships between roles. Out of the box, Cassandra provides org.apache.cassandra.auth.CassandraRoleManager, which stores role information in the system\_auth keyspace. Most functions of the IRoleManager require an authenticated login, so unless the configured IAuthenticator actually implements authentication, most of this functionality will be unavailable. CassandraRoleManager stores role data in the system\_auth keyspace. If you use the role manager, increase system\_auth keyspace replication factor.

**Important:** Use only role manager implementations bundled with DSE.

**roles_validity_in_ms**

( Default: 2000) Fetching permissions can be an expensive operation depending on the authorizer, so this setting allows flexibility. Validity period for roles cache; set to 0 to disable. Granted roles are cached for authenticated sessions in AuthenticatedUser and after the period specified here, become eligible for (async) reload. Disabled automatically for AllowAllAuthorenticator.

**roles_update_interval_in_ms**

( Default: 2000) Enable to refresh interval for roles cache. Defaults to the same value as roles_validity_in_ms. After this interval, cache entries become eligible for refresh. Upon next access, Cassandra schedules an async reload, and returns the
old value until the reload completes. If `roles_validity_in_ms` is non-zero, then this must be also.

**credentials_validity_in_ms**

(Default: 2000) How many milliseconds credentials in the cache remain valid. This cache is tightly coupled to the provided PasswordAuthenticator implementation of `IAuthenticator (page 111)`. If another `IAuthenticator` implementation is configured, Cassandra does not use this cache, and these settings have no effect. Set to 0 to disable.

Related information: Internal authentication (page 118), Internal authorization (page 124)

**Note:** Credentials are cached in encrypted form. This may cause a performance penalty that offsets the reduction in latency gained by caching.

**credentials_update_interval_in_ms**

(Default: same value as `credentials_validity_in_ms`) After this interval, cache entries become eligible for refresh. The next time the cache is accessed, the system schedules an asynchronous reload of the cache. Until this cache reload is complete, the cache returns the old values.

If `credentials_validity_in_ms` is nonzero, this property must also be nonzero.

**permissions_validity_in_ms**

(Default: 2000) How many milliseconds permissions in cache remain valid. Depending on the authorizer, such as CassandraAuthorizer, fetching permissions can be resource intensive. This setting is disabled when set to 0 or when AllowAllAuthorizer is set.

Related information: Object permissions (page 124)

**permissions_update_interval_in_ms**

(Default: same value as `permissions_validity_in_ms (page 113)` (page 86) If enabled, sets refresh interval for the permissions cache. After this interval, cache entries become eligible for refresh. On next access, Cassandra schedules an async reload and returns the old value until the reload completes. If `permissions_validity_in_ms` is nonzero, `roles_update_interval_in_ms` must also be non-zero.

**server_encryption_options**

Enables or disables inter-node encryption. If you enable `server_encryption_options`, you must also generate keys and provide the appropriate key and truststore locations and passwords. There are no custom encryption options currently enabled for Cassandra. Available options:

- **internode_encryption**: (Default: none) Enables or disables encryption of inter-node communication using the `TLS_RSA_WITH_AES_128_CBC_SHA` cipher suite for authentication, key exchange, and encryption of data transfers. Use the DHE/ECDHE ciphers, such as `TLS_DHE_RSA_WITH_AES_128_CBC_SHA`
if running in (Federal Information Processing Standard) FIPS 140 compliant mode. Available inter-node options:

```yaml
# all
Encrypt all inter-node communications.
```

```yaml
# none
No encryption.
```

```yaml
# dc
Encrypt the traffic between the datacenters (server only).
```

```yaml
# rack
Encrypt the traffic between the racks (server only).
```

- **keystore**: (Default: `conf/.keystore`)
  
  The location of a Java keystore (JKS) suitable for use with Java Secure Socket Extension (JSSE), which is the Java version of the Secure Sockets Layer (SSL), and Transport Layer Security (TLS) protocols. The keystore contains the private key used to encrypt outgoing messages.

- **keystore_password**: (Default: `cassandra`)
  
  Password for the keystore.

- **truststore**: (Default: `conf/.truststore`)
  
  Location of the truststore containing the trusted certificate for authenticating remote servers.

- **truststore_password**: (Default: `cassandra`)
  
  Password for the truststore.

The passwords used in these options must match the passwords used when generating the `keystore` and `truststore`. For instructions on generating these files, see Creating a Keystore to Use with JSSE.

The advanced settings:

- **protocol**: (Default: `TLS`)
- **algorithm**: (Default: `SunX509`)
- **store_type**: (Default: `JKS`)
- **cipher_suites**: (Default: `TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA`)
- **require_client_auth**: (Default: `false`
Enables or disables certificate authentication.

Related information: Node-to-node encryption (page 144)

**client_encryption_options**
Enables or disables client-to-node encryption. You must also generate keys and provide the appropriate key and truststore locations and passwords. There are no custom encryption options are currently enabled for Cassandra. Available options:

- **enabled**: (Default: false)
  To enable, set to true.

- **keystore**: (Default: conf/.keystore)
  The location of a Java keystore (JKS) suitable for use with Java Secure Socket Extension (JSSE), which is the Java version of the Secure Sockets Layer (SSL), and Transport Layer Security (TLS) protocols. The keystore contains the private key used to encrypt outgoing messages.

- **keystore_password**: (Default: cassandra)
  Password for the keystore. This must match the password used when generating the keystore and truststore.

- **require_client_auth**: (Default: false)
  Enables or disables certificate authentication. (Available starting with Cassandra 1.2.3.)

- **truststore**: (Default: conf/.truststore)
  Set this property if require_client_auth is true.

- **require_endpoint_verification**: Default: false.
  Enables or disables host name verification.

- **truststore_password**: truststore_password
  Set if require_client_auth is true.

Advanced settings:

- **protocol**: (Default: TLS)
- **algorithm**: (Default: SunX509)
- **store_type**: (Default: JKS)
- **cipher_suites**: (Default: TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA)

Related information: Client-to-node encryption (page 146)
**transparent_data_encryption_options**

Enables encryption of data at rest (on-disk). Recommendation: download and install the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files for your version of the JDK.

Cassandra supports transparent data encryption for the following file types:

- commitlog (page 95)
- hints (page 108)

Available options:

- **enabled**: (Default: false)
- **chunk_length_kb**: (Default: 64)
- **cipher**: options:
  - # AES
  - # CBC
  - # PKCS5Padding
- **key_alias**: testing:1
- **iv_length**: 16
  
  Note: **iv_length** is commented out in the default cassandra.yaml file. Uncomment only if **cipher** is set to AES. The value must be 16 (bytes).

- **key_provider**:
  
  # class_name: org.apache.cassandra.security.JKSKeyProvider

  parameters:
  
  # keystore: conf/.keystore
  # keystore_password: cassandra
  # store_type: JCEKS
  # key_password: cassandra

**ssl_storage_port**

(Default: 7001) The SSL port for encrypted communication. Unused unless enabled in encryption_options.

**native_transport_port_ssl**

(Default: 9142) In Cassandra 3.0 and later, an additional dedicated port can be designated for encryption. If client encryption is enabled and native_transport_port_ssl is disabled, the native_transport_port (default: 9042) will encrypt all traffic. To use both unencrypted and encrypted traffic, enable native_transport_port_ssl

The location of the cassandra-env.sh file depends on the type of installation:

| DataStax Enterprise 5.0 Installer-Services and package installations | /etc/dse/cassandra/cassandra-env.sh |
### Configuration

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-No Services and tarball installations</th>
<th>install_location/resources/cassandra/conf/cassandra-env.sh</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

### Cassandra include file

To set environment variables, Cassandra can use the `cassandra.in.sh` file, located in:

- **Cassandra tarball installations:** `install_location/bin/cassandra.in.sh`
- **Cassandra package installations:** `/usr/share/cassandra/cassandra.in.sh`

### Security

#### Securing Cassandra

Cassandra provides these security features to the open source community.

- **Authentication based on internally controlled rolename/passwords** *(page 118)*

  Cassandra authentication is roles-based and stored internally in Cassandra system tables. Administrators can create, alter, drop, or list roles using CQL commands, with an associated password. Roles can be created with superuser, non-superuser, and login privileges. The internal authentication is used to access Cassandra keyspaces and tables, and by `cqlsh` *(page )* and `DevCenter` *(page )* to authenticate connections to Cassandra clusters and `sstableloader` *(page 388)* to load SSTables.

- **Authorization based on object permission management** *(page 124)*

  Authorization grants access privileges to Cassandra cluster operations based on role authentication. Authorization can grant permission to access the entire database or restrict a role to individual table access. Roles can grant authorization to authorize other roles. Roles can be granted to roles. CQL commands `GRANT` and `REVOKE` are used to manage authorization.

- **Authentication and authorization based on JMX username/passwords** *(page 126)*

  JMX (Java Management Extensions) technology provides a simple and standard way of managing and monitoring resources related to an instance of a Java Virtual Machine (JVM). This is achieved by instrumenting resources with Java objects known as Managed Beans (MBeans) that are registered with an MBean server. JMX authentication stores username and associated passwords in two files, one for passwords and one for access. JMX authentication is used by `nodetool` *(page 250)* and external monitoring tools such as `jconsole`. In Cassandra 3.6 and later, JMX authentication and authorization can be accomplished using Cassandra's internal authentication and authorization capabilities.

- **SSL encryption** *(page 131)*
Cassandra provides secure communication between a client and a database cluster, and between nodes in a cluster. Enabling SSL encryption ensures that data in flight is not compromised and is transferred securely. Client-to-node and node-to-node encryption are independently configured. Cassandra tools (cqlsh, nodetool, DevCenter) can be configured to use SSL encryption. The DataStax drivers can be configured to secure traffic between the driver and Cassandra.

- **General security measures (page 152)**

  Typically, production Cassandra clusters will have all non-essential firewall ports closed. Some ports must be open in order for nodes to communicate in the cluster. These ports are detailed.

### Internal authentication

#### About Internal authentication

Like many databases, Cassandra uses rolenames and passwords for internal authentication. Role-based authentication encompasses both users and roles to bring a number of useful features to authorization. Roles can represent either actual individual users or roles that those users have in administering and accessing the Cassandra cluster.

Figure 18: Roles assigned to individuals and functions

For example, a user named *alice* is created and given login privileges:
CREATE ROLE alice WITH PASSWORD = 'enjoyLife' AND LOGIN = true;

Note that the user is created as a role and this user can log into the database with the assigned password credentials. Roles can be created with superuser, non-superuser, and login privileges. Superuser privileges allow a role to perform any database operations. Next, we create a role that will have been given access to all the functionality of a particular keyspace:

CREATE ROLE cycling_admin WITH PASSWORD = '1234abcd';
GRANT ALL PERMISSIONS ON KEYSpace cycling TO cycling_admin;

This role, when assigned to a user, will provide certain privileges to the user based on the role's privileges; the role that is granted this role will inherit the cycling_admin privileges. The cycling_admin role is granted all permissions on the keyspace cycling in the second command. When alice is granted the role cycling_admin, alice is now granted all permissions on the keyspace cycling:

GRANT cycling_admin TO alice;

An individual user can be granted any number of roles, just as any functional role can be granted another role's permissions. In this example, the role cycling_analyst has the ability to select data, and then gains the ability to select data in the another table hockey when the role hockey_analyst is granted.

CREATE ROLE cycling_analyst WITH PASSWORD = 'zyxw9876';
GRANT SELECT ON TABLE cycling.analysis TO cycling_analyst;
CREATE ROLE hockey_analyst WITH PASSWORD = 'Iget2seeAll';
GRANT SELECT ON TABLE hockey.analysis TO hockey_analyst;
GRANT hockey_analyst TO cycling_analyst;
GRANT cyclist_analyst TO jane;

If a user then is granted the role of cycling_analyst role, that user will be able to select data in the additional table hockey. The illustration above would be modified to show that the user jane now has access to two tables.

Note: Permissions and SUPERUSER status are inherited, but the LOGIN privilege is not.

An important change that roles-based access control also introduces is that the need for SUPERUSER privileges in order to perform user/role management operations is removed. A role can be authorized to create roles or be authorized to grant and revoke permissions:

// Give cycling_accounts the right to create roles
GRANT CREATE ON ALL ROLES TO cycling_accounts;
// Give cycling_accounts the right to grant or revoke permissions
GRANT AUTHORIZE ON KEYSpace cycling TO cycling_accounts;
GRANT cyclist_accounts TO jane;
GRANT cyclist_accounts TO john;

Internal authentication and authorization information is stored in the following Cassandra tables:

system_auth.roles
Table that stores the role name, whether the role can be used for login, whether the role is a superuser, what other roles the role may be a member of, and a bcrypt salted hash password for the role.

**system_auth.role_members**
Table that stores the roles and role members.

**system_auth.role_permissions**
Table that stores the role, a resource (keyspace, table), and the permission that the role has to access the resource.

**system_auth.recqlshSourceole_permissons_index**
Table that stores the role and a resource that the role has a set permission.

Cassandra is configured with a default superuser role and password pair of `cassandra/cassandra` by default. Using this role, additional roles can be created using CQL commands. To secure the system, this default role should be deleted once a non-default superuser has been created.

Once roles and passwords have been set, Cassandra can be configured to use authentication (page 120) in the cassandra.yaml file.

The location of the **cassandra.yaml** file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>installations</td>
<td></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
<tr>
<td>installations</td>
<td></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
</tbody>
</table>

If roles exist and Cassandra is configured to use authentication, Cassandra tools must be executed with optional authentication options.

- `cqlsh` with authentication (page 123)
- DevCenter authenticated connections (page )
- DataStax drivers (page ) - produced and certified by DataStax to work with Cassandra.

**Configuring authentication**

Steps for configuring authentication.

1. Change the authenticator option in the cassandra.yaml file to **PasswordAuthenticator**:

   authenticator: PasswordAuthenticator

   By default, the authenticator option is set to **AllowAllAuthenticator**.

The location of the **cassandra.yaml** file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>installations</td>
<td></td>
</tr>
</tbody>
</table>
2. **Restart Cassandra** *(page 176).*

3. **Start** `cqlsh` **using the default superuser** *(page )** name and password:**
   
   ```
   cqlsh -u cassandra -p cassandra
   ```

4. To ensure that the keyspace is always available, **increase the replication factor** *(page )** for the `system_auth` keyspace to 3 to 5 nodes per datacenter (recommended):**
   
   ```
   cqlsh> ALTER KEYSPACE "system_auth"
   WITH REPLICATION = {
   'class' : 'NetworkTopologyStrategy',
   'dc1' : 3,
   'dc2' : 2};
   ```

   The `system_auth` keyspace uses a QUORUM consistency level when checking authentication for the default `cassandra` user. For all other users created, superuser or otherwise, a LOCAL_ONE consistency level is used for authenticating.

   **Note:** Datacenter names are case sensitive. Verify the case of the using utility, such as `dsetool status`.

   **Caution:** Leaving the default replication factor of 1 set for the `system_auth` keyspace results in denial of access to the cluster if the single replica of the keyspace goes down. For multiple datacenters, be sure to set the replication class to `NetworkTopologyStrategy`.

5. **After increasing the replication factor of a keyspace, run** `nodetool repair` **to make certain the change is propagated:**
   
   ```
   $ nodetool repair system_auth
   ```

6. **Restart Cassandra** *(page 176).*

7. **Start** `cqlsh` **using the superuser name and password:**
   
   ```
   cqlsh -u cassandra -p cassandra
   ```

8. **To prevent security breaches, replace the default superuser, `cassandra`, with another superuser with a different name:**
   
   ```
   cqlsh> CREATE ROLE <new_super_user> WITH PASSWORD = '
   <some_secure_password>'
   ```
The default user cassandra reads with a consistency level (page 56) of QUORUM by default, whereas another superuser reads with a consistency level of LOCAL_ONE.

9. Log in as the newly created superuser:

```
cqlsh -u <new_super_user> -p <some_secure_password>
```

10. The cassandra superuser cannot be deleted from Cassandra. To neutralize the account, change the password to something long and incomprehensible, and alter the user's status to NOSUPERUSER:

```
cqlsh> ALTER ROLE cassandra WITH
       PASSWORD='SomeNonsenseThatNoOneWillThinkOf'
       AND SUPERUSER=false;
```

11. Once you create some new roles, you are ready to authorize those roles (page 124) to access database objects.

12. Fetching role authentication can be a costly operation. To decrease the burden, adjust the validity period for role caching with the roles_validity_in_ms (page 112) option in the cassandra.yaml file (default 2000 milliseconds):

```
roles_validity_in_ms: 2000
```

To disable, set this option to 0. This setting is automatically disabled when the authenticator is set to AllowAllAuthenticator.

13. Configure the refresh interval for role caches by setting the roles_update_interval_in_ms (page 112) option in the cassandra.yaml file (default 2000 ms):

```
roles_update_interval_in_ms: 2000
```

If roles_validity_in_ms is non-zero, this setting must be set.

**Note:** The credentials are cached in their encrypted form.

The following steps apply only to Cassandra 3.4 and later:

14. Fetching credentials authentication can be a costly operation. To decrease the burden, adjust the validity period for credential caching with the credentials_validity_in_ms (page 113) option in the cassandra.yaml file (default 2000 ms):

```
credentials_validity_in_ms: 2000
```
To disable, set this option to 0. This setting is automatically disabled when the authenticator is set to `AllowAllAuthenticator`.

15. To set the refresh interval for credentials caches, use the `credentials_update_interval_in_ms` ([page 113](#)) option (default 2000 ms):

```
credentials_update_interval_in_ms: 2000
```

If `credentials_validity_in_ms` is non-zero, this setting must be set.

16. To disable configuration of authentication and authorization caches (credentials, roles, and permissions) via JMX, uncomment the following line in the `jvm.options` file:

```
-Dcassandra.disable_auth_caches_remote_configuration=true
```

After setting this option, cache options can only be set in the `cassandra.yaml` file. To make the new setting take effect, restart Cassandra.

**Using cqlsh with authentication**

Typically, after configuring authentication, logging into `cqlsh` requires the `-u` and `-p` options to the `cqlsh` command. To set credentials for use when launching `cqlsh`, create or modify the `.cassandra/cqlshrc` file. When present, this file passes default login information to `cqlsh`. The `cqlshrc.sample` file provides an example.

The location of the `cqlshrc.sample` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cqlshrc.sample</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cqlshrc.sample</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cqlshrc.sample</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/conf/cqlshrc.sample</code></td>
</tr>
</tbody>
</table>

1. Create or modify the `cqlshrc` file that specifies a role name and password.

```
[authentication]
username = fred
password = !!bang!!$
```

**Note:** Additional settings in the `cqlshrc` file are described in Creating and using the `cqlshrc` file ([page 126](#)).
2. Save the file in `home/.cassandra` directory and name it `cqlshrc`.

3. Set permissions on the file to prevent unauthorized access, as the password is stored in plain text. The file must be readable by the user that starts `cassandra`.

   ```bash
   $ chmod 440 home/.cassandra/cqlshrc
   ```

4. Check the permissions on `home/.cassandra/cqlshrc_history` to ensure that plain text passwords are not compromised.

**Internal authorization**

**Object permissions**

Object permissions may be assigned using Cassandra's internal authorization mechanism for the following objects:

- keyspace
- table
- function
- aggregate
- roles
- MBeans (in Cassandra 3.6 and later)

Authenticated roles with passwords stored in Cassandra are authorized selective access. The permissions are stored in Cassandra tables *(page 119)*.

Permission is configurable *(page  )* for CQL commands `CREATE`, `ALTER`, `DROP`, `SELECT`, `MODIFY`, and `DESCRIBE`, which are used to interact with the database. The `EXECUTE` command may be used to grant permission to a role for the `SELECT`, `INSERT`, and `UPDATE` commands. In addition, the `AUTHORIZE` command may be used to grant permission for a role to `GRANT`, `REVOKE` or `AUTHORIZE` another role's permissions.

Read access to these system tables is implicitly given to every authenticated user or role because the tables are used by most Cassandra tools:

- `system_schema.keyspaces`
- `system_schema.columns`
- `system_schema.tables`
- `system.local`
- `system.peers`

**Configuring internal authorization**

CassandraAuthorizer is one of many possible IAuthorizer implementations. Its advantage is that it stores permissions in the `system_auth.permissions` table to support all
authorization-related CQL statements. To activate it, change the `authorizer` option in `cassandra.yaml` to use the `CassandraAuthorizer`.

**Note:** To configure authentication, see Internal authentication *(page 118)*.

The location of the `cassandra.yaml` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball</td>
<td><code>install_location/resources/cassandra/</code></td>
</tr>
<tr>
<td>Installations</td>
<td><code>conf/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/resources/cassandra/</code></td>
</tr>
<tr>
<td></td>
<td><code>conf/cassandra.yaml</code></td>
</tr>
</tbody>
</table>

1. In the `cassandra.yaml` file, comment out the default `AllowAllAuthorizer` and add the `CassandraAuthorizer`.

   ```yaml
   authorizer: CassandraAuthorizer
   ```

   You can use any authenticator except AllowAll.

2. **Increase the replication factor** *(page 121)* for the `system_auth` keyspace if not already configured.

3. Fetching role permissions can be a costly operation. Role permissions can be cached to decrease the burden. Adjust the validity period for permission caching by setting the `permissions_validity_in_ms` *(page 113)* option in the `cassandra.yaml` file. The default value is 2000 milliseconds. The caching can be disabled by setting the option to 0. This setting is disabled automatically if the authorizer is set to `AllowAllAuthorizer`.

   ```yaml
   permissions_validity_in_ms: 2000
   ```

4. A refresh interval for role caches can also be configured by setting the `permissions_update_interval_in_ms` *(page 113)* option in the `cassandra.yaml` file. The default value is the same value as the `permissions_validity_in_ms` setting. If `permissions_validity_in_ms` is non-zero, this setting must be set.

   ```yaml
   permissions_update_interval_in_ms: 2000
   ```

CQL supports these authorization statements:

- **GRANT** *(page )
- **LIST PERMISSIONS** *(page )
JMX authentication and authorization

JMX Authentication and Authorization

JMX authentication and authorization allows selective users to access JMX tools and JMX metrics. In Cassandra 3.5 and earlier, JMX is configured with password and access files. In Cassandra 3.6 and later, JMX connections can use the same internal authentication and authorization mechanisms as CQL clients.

If usernames and passwords exist and Cassandra is configured to use authentication and authorization, JMX tools must be executed with authentication and authorization options.

• nodetool with authentication (page 130)
• jconsole with authentication (page 131)

Enabling JMX authentication and authorization

By default, JMX security is disabled and accessible only from localhost without authentication as shown in the following lines from the cassandra-env.sh file:

```
if [ "$LOCAL_JMX" = "yes" ]; then
  JVM_OPTS="$JVM_OPTS -Dcassandra.jmx.local.port=$JMX_PORT -XX:+DisableExplicitGC"
```

Configuring JMX authentication and authorization can be accomplished using local password and access files to set the usernames, passwords and access permissions. In Cassandra 3.6 and later, Cassandra’s internal authentication and authorization can optionally be configured for JMX security.

These two methods work for remote authentication and authorization; the difference is just the location of the configuration settings in the cassandra-env.sh file. Local configuration is placed within the `if ["$LOCAL_JMX" = "yes"]; then` block in the file, whereas remote configuration is placed with the `else` block.

AUTHENTICATION AND AUTHORIZATION USING LOCAL FILES

• By default, JMX security is disabled and accessible only from localhost as shown in the following lines from the cassandra-env.sh file:

```
if [ "$LOCAL_JMX" = "yes" ]; then
  JVM_OPTS="$JVM_OPTS -Dcassandra.jmx.local.port=$JMX_PORT -XX:+DisableExplicitGC"
```

• Change $LOCAL_JMX to no. Add the following lines in the remote block in the cassandra-env.sh file:

```
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.authenticate=true"
```
• Create a password file and add the user and password for JMX-compliant utilities, specifying the credentials for your environment. The default location of the password file in the cassandra-env.sh is /etc/cassandra/jmxremote.password.

cassandra cassandra
<new_superuser> <new_superuser_password>
<some_other_user> <some_other_user_password>
controlRole someOtherHardToRememberPassword

**Important:** The default superuser account is a security hazard! This account is used only for the purposes of illustration.

• The password file must be secured from unauthorized readers. Change the ownership of the jmxremote.password file to the user who starts cassandra and change permissions to read only:

```
$ chown cassandra:cassandra /etc/cassandra/jmxremote.password
$ chmod 400 /etc/cassandra/jmxremote.password
```

This example presumes that cassandra is run by the default user cassandra.

• Create an access file and enter the following information. The default location of the access file in the cassandra-env.sh is /etc/cassandra/jmxremote.access.

cassandra readwrite
<new_superuser> readwrite
<some_other_user> readonly
controlRole readwrite \
create javax.management.monitor.,javax.management.timer. \
unregister

**Important:** The default superuser account is a security hazard! This account is used only for the purposes of illustration.

The **readonly** permission allows the JMX client to read an MBean's attributes and receive notifications. The **readwrite** permission allows the JMX client to set attributes, invoke operations, and create and remove MBeans, in addition to reading an MBean's attributes and receives notifications.

• The access file must be secured from unauthorized readers. Change the ownership of the jmxremote.access file to the user who starts cassandra and change permissions to read only:

```
$ chown cassandra:cassandra /etc/cassandra/jmxremote.access
$ chmod 400 /etc/cassandra/jmxremote.access
```
This example presumes that cassandra is run by the default user cassandra.

- **Restart Cassandra (page 176)** to make the change effective.
- Check that nodetool status requires the username and password in order to execute. The command should fail without authentication if everything is configured correctly.

```
$ nodetool status
```

- Run nodetool status with the cassandra user and password.

```
$ nodetool -u cassandra -pw cassandra status
```

**AUTHENTICATION AND AUTHORIZATION WITH CASSANDRA INTERNALS - CASSANDRA 3.6 AND LATER**

- By default, JMX security is disabled and accessible only from localhost as shown in the following lines from the cassandra-env.sh file:

```
if [ "$LOCAL_JMX" = "yes" ]; then
  JVM_OPTS="$JVM_OPTS -Dcassandra.jmx.local.port=$JMX_PORT -XX:+DisableExplicitGC"
```

- Comment out the existing line and add or uncomment the following lines in either the local or remote block in the cassandra-env.sh file:

```
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.authenticate=true"
JVM_OPTS="$JVM_OPTS -Dcassandra.jmx.remote.login.config=CassandraLogin"
JVM_OPTS="$JVM_OPTS -Djava.security.auth.login.config=$CASSANDRA_HOME/conf/cassandra-jaas.config"
JVM_OPTS="$JVM_OPTS -Dcassandra.jmx.authorizer=org.apache.cassandra.auth.jmx.AuthorizationProxy"
```

- And comment out the following lines in the cassandra-env.sh file:

```
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.password.file=/etc/cassandra/jmxremote.password"
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.access.file=/etc/cassandra/jmxremote.access"
```

- Change authentication in the cassandra.yaml file to PasswordAuthenticator.

```
authenticator: PasswordAuthenticator
```

- Change authorization in the cassandra.yaml file to CassandraAuthorizer.

```
authorizer: CassandraAuthorizer
```

- **Restart Cassandra (page 176)** to make the change effective.
- Check that `nodetool status` requires the username and password in order to execute. The command should fail without authentication if everything is configured correctly.

```bash
$ nodetool -u cassandra -pw cassandra status
```

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra-env.sh</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra-env.sh</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra-env.sh</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/conf/cassandra-env.sh</code></td>
</tr>
</tbody>
</table>

- **Cassandra authorization** *(page 124)* can be used to grant and revoke permissions to database objects, including MBeans.

**SPECIFYING JMX AUTHENTICATION ON COMMAND LINE**

- Generally, JMX settings are inserted into the `cassandra-env.sh` file. However, these options can be specified at the command line:

```bash
cassandra -Dcom.sun.management.jmxremote.authenticate=true -Dcom.sun.management.jmxremote.password.file=/etc/cassandra/jmxremote.password
```

If you run `nodetool status` without user and password when authentication and authorization are configured, you'll see an error similar to:

```
Exception in thread "main" java.lang.SecurityException: Authentication failed! Credentials required
  at com.sun.jmx.remote.security.JMXPluggableAuthenticator.authenticationFailure(Unknown Source)
  at com.sun.jmx.remote.security.JMXPluggableAuthenticator.authenticate(Unknown Source)
  at sun.management.jmxremote.ConnectorBootstrap$AccessFileCheckerAuthenticator.authenticate(Unknown Source)
  at javax.management.remote.rmi.RMIServerImpl.doNewClient(Unknown Source)
  at javax.management.remote.rmi.RMIServerImpl.newClient(Unknown Source)
  at sun.reflect.NativeMethodAccessorImpl.invoke0(Native Method)
  at sun.reflect.NativeMethodAccessorImpl.invoke(Unknown Source)
  at sun.reflect.DelegatingMethodAccessorImpl.invoke(Unknown Source)
  at java.lang.reflect.Method.invoke(Unknown Source)
  at sun.rmi.server.UnicastServerRef.dispatch(Unknown Source)
  at sun.rmi.transport.Transport$1.run(Unknown Source)
  at sun.rmi.transport.Transport$1.run(Unknown Source)
  at java.security.AccessController.doPrivileged(Native Method)
```
Using nodetool with authentication

After configuring JMX authentication, using `nodetool` requires the `-u` and `-p` options to the `nodetool` commands.

1. Run `nodetool` using a pre-configured JMX username and password for `<username>` and `<password>`:

   ```
   $ nodetool -u <username> -pw <password>
   ```

   For Cassandra 3.6 and later, the username and password can be an internally configured Cassandra role and password.
Note: In Cassandra 3.0.8 and later, a user designated readonly access can run nodetool info so that cluster monitoring is available. In earlier versions, the user must have readwrite permission.

Using jconsole with authentication

After configuring JMX authentication, using jconsole requires a username and password to complete the remote connection to the Cassandra cluster. Use an appropriate username/password combination.

1. Start jconsole using a pre-configured JMX username and password for <username> and <password>:

![New Connection](image)

For Cassandra 3.6 and later, the username and password can be an internally configured Cassandra role and password.

SSL encryption

Encrypting Cassandra with SSL

The Secure Socket Layer (SSL) is a cryptographic protocol used to secure communications between computers. For reference, see SSL in wikipedia. Data is encrypted during communication to prevent accidental or deliberate attempts to read the data.

Briefly, SSL works in the following manner. Two entities, either software or hardware, that are communicating with one another. The entities an be a client and node or peers in a
cluster. These entities must exchange information to set up trust between them. Each entity that will provide such information must have a generated key that consists of a private key that only the entity stores and a public key that can be exchanged with other entities. If the client wants to connect to the server, the client requests the secure connection and the server sends a certificate that includes its public key. The client checks the validity of the certificate by exchanging information with the server, which the server validates with its private key. If a two-way validation is desired, this process must be carried out in both directions. Private keys and certificates are stored in the keystore and public keys are stored in the truststore. For systems using a Certificate Authority (CA), the truststore can store certificates signed by the CA for verification. Both keystores and truststores have passwords assigned, referred to as the keypass and storepass.

Apache Cassandra provides these SSL encryption features for .

- **Node-to-node encrypted communication** *(page 144)*
  
  Node-to-node, or internode, encryption is used to secure data passed between nodes in a cluster.

- **Client-to-node encrypted communication** *(page 146)*
  
  Client-to-node encryption is used to secure data passed between a client program, such as *cqlsh* *(page 148)*, *DevCenter* *(page )* , or *nodetool* *(page 149)*, and the nodes in the cluster.

### Installing Java Cryptography Extension (JCE) Files

Installing the JCE Unlimited Strength Jurisdiction Policy Files can ensure support for all encryption algorithms when using Oracle Java with SSL on Apache Cassandra, and it highly recommended. The files must be installed on every node in the Cassandra cluster.

Some of the cipher suites in the default *cassandra.yaml* file are included only in the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files. To ensure support for all encryption algorithms, install the JCE Unlimited Strength Jurisdiction Policy Files.

The location of the *cassandra.yaml* *(page )* file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
</tbody>
</table>

Install the JCE files using the appropriate method for your Cassandra installation:

**Installing the JCE on RHEL-based systems**

1. If necessary, install the EPEL repository:
$ sudo yum install epel-release

2. Installing the JCE using the Oracle JAR files:

   a. Download the Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files from Oracle Java SE download page under Additional Resources.

   b. Unzip the downloaded file.

   c. Copy local_policy.jar and US_export_policy.jar to the $JAVA_HOME/jre/lib/security directory to overwrite the existing jar files.

Installing the JCE on Debian-based systems

Install JCE using webupd8 PPA repository:

$ sudo apt-get install oracle-java8-unlimited-jce-policy

Preparing server certificates for development

To use SSL encryption for client-to-node encryption or node-to-node encryption, SSL certificates must be generated using keytool. If you generate the certificates for one type of encryption, you do not need to generate them again for the other; the same certificates are used for both. All nodes must have all the relevant SSL certificates on all nodes. A keystore contains private keys. The truststore contains SSL certificates for each node. The certificates in the truststore don't require signing by a trusted and recognized public certification authority.

• Generate a private and public key pair on each node of the cluster. Use an alias that identifies the node. Prompts for the keystore password, dname (first and last name, organizational unit, organization, city, state, country), and key password. The dname should be generated with the CN value as the IP address or FQDN for the node.

$ keytool -genkey -keyalg RSA -alias node0 -validity 36500 -keystore keystore.node0

   Note: In this example, the value for --validity gives this key pair a validity period of 100 years. The default validity value for a key pair is 90 days.

• The generation command can also include all prompted-for information in the command line. This example uses an alias of node0, a keystore name of keystore.node0, uses the same password of cassandra for both the keystore and the key, and a dname that identifies the IP address of node0 as 172.31.10.22.

$ keytool -genkey -keyalg RSA -alias node0 -keystore keystore.node0 -storepass cassandra -keypass cassandra -dname "CN=172.31.10.22, OU=None, O=None, L=None, C=None"
• **Export the public part of the certificate to a separate file.**

```bash
$ keytool -export -alias cassandra -file node0.cer -keystore .keystore
```

• **Add the node0.cer certificate to the node0 truststore of the node using the keytool -import command.**

```bash
$ keytool -import -v -trustcacerts -alias node0 -file node0.cer -keystore truststore.node0
```

• **cqlsh does not work with the certificate in the format generated. openssl is used to generate a PEM file of the certificate with no keys, node0.cer.pem, and a PEM file of the key with no certificate, node0.key.pem. First, the keystore is imported in PKCS12 format to a destination keystore, node0.p12, in the example. This is followed by the two commands that extract the two PEM files.**

```bash
$ keytool -importkeystore -srckeystore keystore.node0 -destkeystore node0.p12 -deststoretype PKCS12 -srcstorepass cassandra -deststorepass cassandra
openssl pkcs12 -in node0.p12 -nokeys -out node0.cer.pem -passin pass:cassandra
openssl pkcs12 -in node0.p12 -nodes -nocerts -out node0.key.pem -passin pass:cassandra
```

• **For client-to-remote-node encryption or node-to-node encryption, use a copying tool such as scp to copy the node0.cer file to each node. Import the file into the truststore after copying to each node. The example imports the certificate for node0 into the truststore for node1.**

```bash
$ keytool -import -v -trustcacerts -alias node0 -file node0.cer -keystore truststore.node1
```

• **Make sure keystore file is readable only to the Cassandra daemon and not by any user of the system.**

• **Check that the certificates exist in the keystore and truststore files using keytool -list. The example shows checking for the node1 certificate in the keystore file and for the node0 and node1 certificates in the truststore file.**

```bash
$ keytool -list -keystore keystore.node1
keytool -list -keystore truststore.node1
```

• **Import the user's certificate into every node's truststore using keytool:**

```bash
$ keytool -import -v -trustcacerts -alias <username> -file <certificate file> -keystore .truststore
```

### Preparing SSL certificates for production

To use SSL encryption for client-to-node encryption or node-to-node encryption, SSL certificates must be generated using `openssl` and `keytool`. To validate the certificates, a
self-signed Certificate Authority (CA) can be generated for production use with Apache Cassandra. The certificates generated using these instructions can be used for both internode and client-to-node encryption. For internode encryption, all nodes must have the truststore that provides the chain of trust for the CA. The certificates in the truststore can either be signed by the self-signed certificate authority used here or by a trusted and recognized public certificate authority.

Create a root CA certificate and key

1. Create the root CA certificate and key using `openssl req`. This command uses a certificate configuration file `gen_rootCa_cert.conf`.

   ```
   $ openssl req
   -config gen_rootCa_cert.conf
   -new -x509 -nodes
   -subj /CN=rootCa/OU=TestCluster/O=YourCompany/C=US/
   -keyout rootCa.key
   -out rootCa.crt
   -days 365
   # gen_rootCa_cert.conf
   [ req ]
   distinguished_name = req_distinguished_name
   prompt = no
   output_password = myPass
   default_bits = 2048
   
   [ req_distinguished_name ]
   C = US
   O = YourCompany
   OU = TestCluster
   CN = rootCa
   
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-config</td>
<td>Configuration file to use</td>
</tr>
<tr>
<td>-new</td>
<td>Generate new certificate</td>
</tr>
<tr>
<td>-x509</td>
<td>Outputs a self-signed certificate</td>
</tr>
<tr>
<td>-nodes</td>
<td>If a private key is created, it is not encrypted</td>
</tr>
<tr>
<td>-subj</td>
<td>Sets subject name when processing</td>
</tr>
<tr>
<td>-keyout</td>
<td>Specify the private key filename to write</td>
</tr>
<tr>
<td>-out</td>
<td>Specify the certificate filename to write</td>
</tr>
<tr>
<td>-days</td>
<td>Specify the number of days for which to certify the certificate</td>
</tr>
</tbody>
</table>
   
   The resulting files are the rootCA certificate and the rootCa private key.
An example of the rootCa.crt file:

-----BEGIN CERTIFICATE-----
MIIDADCCAgCCQwl1PhaMCuqNDAnBgkqhkiG9w0BAQsFA8BCMQswCQYDVQQGEwJD

-----END PRIVATE KEY-----

Apache Cassandra 3.0 for DSE 5.0 (Earlier version)
Verify the rootCa certificate

2. Verify the rootCa certificate.

$ openssl x509
   -in rootCa.crt
   -text
   -noout

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-in</td>
<td>Specify the certificate filename to verify</td>
</tr>
<tr>
<td>-text</td>
<td>Print out the certificate in text form including the public key, signature algorithms, issuer and subject names, serial number any extensions present and any trust settings</td>
</tr>
<tr>
<td>-noout</td>
<td>Prevents output of the encoded version of the request</td>
</tr>
</tbody>
</table>

This command prints output to the console that is similar to this example:

Certificate:
   Data:
      Version: 1 (0x0)
      Serial Number: 10851234054762703412 (0x969753e168c0aa34)
      Signature Algorithm: sha256WithRSAEncryption
      Issuer: C=US, O=YourCompany, OU=TestCluster, CN=rootCa

Generate public/private key pair and keystore for each node

3. Repeat this command for each node. The files can be generated on a single node and distributed out to the nodes after the entire process is completed.

$ keytool -genkeypair
   -keyalg RSA
   -alias 10.200.175.15
   -keystore 10.200.175.15.jks
   -storepass myKeyPass
   -keypass myKeyPass
   -validity 365
   -keysize 2048
   -dname "CN=10.200.175.15, OU=TestCluster, O=YourCompany, C=US"

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-genkeypair</td>
<td>Command to generate a public/private key pair</td>
</tr>
<tr>
<td>-keyalg</td>
<td>Specify the key algorithm</td>
</tr>
<tr>
<td>-alias</td>
<td>Assign an unique alias by which keystore entry is accessed</td>
</tr>
<tr>
<td>-keystore</td>
<td>Specify the keystore filename</td>
</tr>
<tr>
<td>-storepass</td>
<td>Specify the keystore password</td>
</tr>
</tbody>
</table>
- **keypass** - Specify the private key password
  - **validity** - Specify the number of days for the keystore certificate validity
  - **keysize** - Specify the size of the generated key
  - **dname** - Specify the X.500 Distinguished Name to be associated with the value of alias

In this example, the node IP address is 10.200.175.15 and the keystore filename incorporates that IP address with a suffix of .jks (Java KeyStore). While the keystore can be named with any convention, the examples here use the IP address in order to map the files to the nodes. The **dname** sets the **CN** value to the node's IP address or FQDN as well. The **storepass** and **keypass** must be the same value.

### Check certificates

4. The certificates can be checked once generated:

```
$ keytool -list
  -keystore 10.200.175.15.jks
  -storepass myKeyPass
```

An example keystore file:

```
Keystore type: JKS
Keystore provider: SUN

Your keystore contains 1 entry

10.200.175.15, Sep 10, 2016, PrivateKeyEntry,
Certificate fingerprint (SHA1):
```

### Export certificate signing request (CSR) for each node

5. Once the node certificate and key are generated, a certificate signing request (CSR) is exported. The CSR will be signed with the rootCa certificate to verify that the node's certificate is trusted.

```
$ keytool -certreq
  -keystore 10.200.175.15.jks
  -alias 10.200.175.15
  -file 10.200.175.15.csr
  -keypass myKeyPass
  -storepass myKeyPass
  -dname "CN=10.200.175.15, OU=TestCluster, O=YourCompany, C=US"
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-keypass</td>
<td>Specify the private key password</td>
</tr>
<tr>
<td>-validity</td>
<td>Specify the number of days for the keystore</td>
</tr>
<tr>
<td>-keysize</td>
<td>Specify the size of the generated key</td>
</tr>
<tr>
<td>-dname</td>
<td>Specify the X.500 Distinguished Name to be</td>
</tr>
<tr>
<td></td>
<td>associated with the value of alias</td>
</tr>
</tbody>
</table>
Configuration

- `certreq`: Command to export a CSR
- `file`: Specify the CSR filename
- `alias`: Assign an unique alias by which keystore entry is accessed
- `keystore`: Specify the keystore filename
- `storepass`: Specify the keystore password
- `keypass`: Specify the private key password
- `dname`: Specify the X.500 Distinguished Name to be associated with the value of alias

An example CSR file:

```

-----END CERTIFICATE-----
```

Verify the signed certificate for each node

7. Check the signed certificate by designating the rootCa certificate and the signed certificate to verify:
Configuration

openssl verify -CAfile rootCa.crt 10.200.175.15.crt_signed

If the verification succeeds, a console message is returned:

10.200.175.15.crt_signed: OK

Import rootCa certificate to each node keystore

8. Use `keytool -importcert` to import the rootCa certificate into each node keystore:

```
$ keytool -importcert
    -keystore 10.200.175.15.jks
    -alias rootCa
    -file rootCa.crt
    -noprompt
    -keypass myKeyPass
    -storepass myKeyPass
```

The `-noprompt` option allows the command to use the specified values rather than prompting for input.

The keystore file now has two entries, one for the rootCa certificate and one for the node certificate:

```
Keystore type: JKS
Keystore provider: SUN

Your keystore contains 2 entries

rootca, Sep 10, 2016, trustedCertEntry,
Certificate fingerprint (SHA1):
10.200.175.15, Sep 10, 2016, PrivateKeyEntry,
Certificate fingerprint (SHA1):
```

Import node's signed certificate into node keystore for each node

9.

```
$ keytool -importcert
    -keystore 10.200.175.15.jks
    -alias 10.200.175.15
    -file 10.200.175.15.crt_signed
    -noprompt
    -keypass myKeyPass
    -storepass myKeyPass
```
The resulting file will appear similar to the result from the previous step, but the node certificate originally created is replaced with the signed node certificate.

**Create a server truststore**

10. A server truststore file can be used to establish a chain of trust between the nodes of the cluster.

```
$ keytool -importcert
   -keystore generic-server-truststore.jks
   -alias rootCa
   -file rootCa.crt
   -noprompt
   -keypass myPass
   -storepass truststorePass
```

The resulting truststore file can be inspected using the `keytool -list` command:

```
$ keytool -list
   -keystore generic-server-truststore.jks
   -storepass truststorePass
```

and an example of the truststore file will include a rootCa certificate entry:

```
Keystore type: JKS
Keystore provider: SUN

Your keystore contains 1 entry

rootca, Sep 10, 2016, trustedCertEntry,
Certificate fingerprint (SHA1):
```

**Copy the truststore file to each node**

11. The truststore file must be copied to each node. If a node is used to generate the file, copy the file to a location of choice and name the file with a standard format, such as `server-truststore.jks`. This example shows the copy command for a Linux server with a tarball installation of Cassandra and stores the file in the configuration directory of Cassandra:

```
$ cp ~/generic-server-truststore.jks /usr/local/lib/cassandra/conf/server-truststore.jks
```

**Copy the each node keystore file to each node**

12. Each node file must have a copy of its keystore file. If a node is used to generate the file, copy the file to a location of choice. This example shows the secure remote copy commands for a Linux server with a tarball installation of Cassandra, where the
certificates were generated on a single node. The file is stored in the configuration directory of Cassandra in this example:

```
$ scp -r 10.200.175.150.jks /usr/local/lib/cassandra/conf/10.200.175.150.jks
```

**Node-to-node encryption**

Node-to-node encryption protects data transferred between nodes in a cluster, including gossip communications, using SSL (Secure Sockets Layer).

**Prerequisites:** Prepare SSL certificates with a self-signed CA (page 134) for production, or prepare SSL certificates (page 133) for development.

To enable node-to-node SSL, you must set the `server_encryption_options` (page 113) in the cassandra.yaml file.

The location of the cassandra.yaml (page 134) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>File Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

**Enable server_encryption_options on each node**

1. Modify the cassandra.yaml file with the following settings:

   **For production clusters:**

   ```
   server_encryption_options:
     internode_encryption: all
     keystore: /usr/local/lib/cassandra/conf/server-keystore.jks
     keystore_password: myKeyPass
     truststore: /usr/local/lib/cassandra/conf/server-truststore.jks
     truststore_password: truststorePass
     # More advanced defaults below:
     protocol: TLS
     algorithm: SunX509
     store_type: JKS
     cipher_suites: [TLS_RSA_WITH_AES_256_CBC_SHA]
     require_client_auth: true
   ```

   This file uses the certificates prepared with a self-signed CA (page 134).

   **Note:** `cipher_suites` can be configured for FIPS-140 compliance (page 113) if required.

   **For development clusters:**
server_encryption_options:
    internode_encryption: all
    keystore: /conf/keystore.node0
    keystore_password: cassandra
    truststore: /conf/truststore.node0
    truststore_password: cassandra
# More advanced defaults below:
    protocol: TLS
    algorithm: SunX509
    store_type: JKS
    cipher_suites: [TLS_RSA_WITH_AES_256_CBC_SHA]
    require_client_auth: true

This file uses the certificates prepared for development (page 133).

Internode encryption can be set to four different choices:

all
    All traffic is encrypted.
none
    No traffic is encrypted.
dc
    Traffic between datacenters is encrypted.
rack
    Traffic between racks is encrypted.

Set appropriate paths to the keystore and truststore files. Set the passwords to
the passwords set during keystore and truststore generation. If two-way certificate
authentication is desired, set require_client_auth to true.

Restart cassandra

2. Restart cassandra to make changes effective.

$ kill -9 cassandra_pid
$ cassandra

3. Check the logs to discover if SSL encryption has been started. On Linux, use the grep
command:

$ grep SSL install_location/logs/system.log

The resulting line will be similar to this example:
Client-to-node encryption

Client-to-node encryption protects data in flight from client machines to a database cluster using SSL (Secure Sockets Layer). It establishes a secure channel between the client and the coordinator node.

The location of the cassandra.yaml (page 104) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>File Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>installations</td>
<td></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

**Prerequisites:** Prepare SSL certificates with a self-signed CA (page 134) for production, or prepare SSL certificates (page 133) for development.

To enable client-to-node SSL, set the client_encryption_options (page 115) in the cassandra.yaml file.

On each node under **client_encryption_options**:

1. Enable encryption.

**Enable client_encryption_options on each node**

2. Modify the cassandra.yaml file with the following settings:

   **For production clusters:**

   ```
   client_encryption_options:
   enabled: true
   # If enabled and optional is set to true encrypted and unencrypted connections are handled.
   optional: false
   keystore: /usr/local/lib/cassandra/conf/server-keystore.jks
   keystore_password: myKeyPass
   require_client_auth: true
   # Set trustore and truststore_password if require_client_auth is true
   truststore: /usr/local/lib/cassandra/conf/server-truststore.jks
   truststore_password: truststorePass
   protocol: TLS
   algorithm: SunX509
   store_type: JKS
   ```
cipher_suites: [TLS_RSA_WITH_AES_256_CBC_SHA]

This file uses the certificates prepared with a self-signed CA (page 134).

For development clusters:

client_encryption_options:
  enabled: true
  # If enabled and optional is set to true encrypted and
  # unencrypted connections are handled.
  optional: false
  keystore: conf/keystore.node0
  keystore_password: cassandra
  require_client_auth: true
  # Set trustore and truststore_password if require_client_auth is
  true
  truststore: conf/truststore.node0
  truststore_password: cassandra
  protocol: TLS
  algorithm: SunX509
  store_type: JKS
  cipher_suites: [TLS_RSA_WITH_AES_256_CBC_SHA]

This file uses the certificates prepared for development (page 133).

Set appropriate paths to the keystore and truststore files. Set the passwords to the passwords set during keystore and truststore generation. If two-way certificate authentication is desired, set require_client_auth to true. Enabling two-way certificate authentication allows tools to connect to a remote node. For local access to run cqlsh on a local node with SSL encryption, require_client_auth can be set to false

Enabling client encryption will encrypt all traffic on the native_transport_port (default: 9042). If both encrypted and unencrypted traffic is required, an additional cassandra.yaml setting must be enabled. The native_transport_port_ssl (default: 9142) sets an additional dedicated port to carry encrypted transmissions, while native_transport_port carries unencrypted transmissions.

Note: It is beneficial to install the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files if this option is enabled.

Restart cassandra

3. Restart cassandra to make changes effective.

$ kill -9 cassandra_pid
$ cassandra

**Using cqlsh with SSL**

Using a `cqlshrc` file is the easiest method of getting `cqlshrc` settings. The `cqlshrc.sample` provides an example that can be copied as a starting point.

The location of the `cqlshrc.sample` file depends on the type of installation:

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>
<th>/etc/dse/cassandra/cqlshrc.sample</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cqlshrc.sample</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cqlshrc.sample</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cqlshrc.sample</td>
</tr>
</tbody>
</table>

**Prerequisites:** Prepare SSL certificates with a self-signed CA (page 134) for production, or prepare SSL certificates (page 133) for development. Additionally, configure client-to-node encryption (page 146).

1. To run cqlsh with SSL encryption, create a `.cassandra/cqlshrc` file in with the following settings:

```
[authentication]
username = fred
password = !!bang!!$

[connection]
hostname = 127.0.0.1
port = 9042

[ssl]
certfile = ~/keys/cassandra.cert
validate = false ;; Optional, true by default. See the paragraph below.

certfiles ;; Optional section, overrides the default certfile in the [ssl] section.
  10.209.182.160 = /etc/dse/cassandra/conf/dsenode0.cer
  10.68.65.199 = /etc/dse/cassandra/conf/dsenode1.cer
```

When `validate` is enabled, to verify that the certificate is trusted the host in the certificate is compared to the host of the machine to which it is connected. Note that the rootCa certificate and key are supplied to access the trustchain. The SSL certificate must be provided either in the configuration file or as an environment
variable. The environment variables (`SSL_CERTFILE` and `SSL_VALIDATE`) override any options set in this file.

Note: Additional settings in the `cqlshrc` file are described in Creating and using the `cqlshrc` file (page ).

An optional section, `[certfiles]`, will override the default `certfile` in the `[ssl]` section. The use of the same IP addresses in the `[certfiles]` section, as is used to generate the `dname` of the certificates, is required for two-way SSL encryption. Each node must have a line in the `[certfiles]` section for client-to-remote-node or node-to-node. Using `certfiles` is more common for development clusters.

2. Start `cqlsh (page )` with the `--ssl` option for `cqlsh` to local node encrypted connection.

```
cqlsh --ssl ## Package installations
$ install_location/bin/cqlsh --ssl ## Tarball installations
```

3. A username and password can also be supplied at `cqlsh (page )` startup. This example provides the username `cassandra` with password `cassandra`.

```
cqlsh --ssl ## Package installations
$ install_location/bin/cqlsh --ssl -u cassandra -p cassandra ##
     Tarball installations
```

Note that a username and password can be entered in the `cqlshrc` file so that it will be automatically read each time `cqlsh` is started.

4. For a remote node encrypted connection, start `cqlsh (page )` with the `--ssl` option and an IP address:

```
cqlsh --ssl ## Package installations
$ install_location/bin/cqlsh --ssl 172.31.10.22 ## Tarball
     installations
```

Using nodetool (JMX) with SSL encryption

Using `nodetool` with SSL requires some JMX setup. Changes to `cassandra-env.sh` are required, and a configuration file, `~/.cassandra/nodetool-ssl.properties`, is created.

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>File Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra-env.sh</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra-env.sh</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra-env.sh</code></td>
</tr>
</tbody>
</table>
Prerequisites: Prepare SSL certificates with a self-signed CA (page 134) for production, or prepare SSL certificates (page 133) for development. Additionally, configure client-to-node encryption (page 146).

1. First, follow steps #1-8 in Enabling JMX authentication and authorization (page 126) if authentication and authorization are required.

2. To run nodetool with SSL encryption, some additional changes are required to cassandra-env.sh. The following settings must be added to the file. Use the file path to the keystore and truststore, and appropriate passwords for each file. These changes must be made on each node in the cluster.

For production:

```bash
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.ssl=true"
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.ssl.need.client.auth=true"
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.registry.ssl=true"
#JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.ssl.enabled.protocols=<enabled-protocols>"
#JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.ssl.enabled.cipher.suites=<enabled-cipher-suites>"
JVM_OPTS="$JVM_OPTS -Djavax.net.ssl.keyStore=/usr/local/lib/cassandra/conf/server-keystore.jks"
JVM_OPTS="$JVM_OPTS -Djavax.net.ssl.keyStorePassword=myKeyPass"
JVM_OPTS="$JVM_OPTS -Djavax.net.ssl.trustStore=/usr/local/lib/cassandra/conf/server-truststore.jks"
JVM_OPTS="$JVM_OPTS -Djavax.net.ssl.trustStorePassword=truststorePass"
```

For development:

```bash
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.ssl=true"
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.ssl.need.client.auth=true"
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.registry.ssl=true"
#JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.ssl.enabled.protocols=<enabled-protocols>"
#JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.ssl.enabled.cipher.suites=<enabled-cipher-suites>"
JVM_OPTS="$JVM_OPTS -Djavax.net.ssl.keyStore=keystore.node0"
JVM_OPTS="$JVM_OPTS -Djavax.net.ssl.keyStorePassword=cassandra"
JVM_OPTS="$JVM_OPTS -Djavax.net.ssl.trustStore=truststore.node0"
```
Enable SSL for JMX by setting `com.sun.management.jmxremote.ssl` to true. If two-way certificate authentication is desired, set `com.sun.management.jmxremote.ssl.need.client.auth` to true. If `com.sun.management.jmxremote.registry.ssl` is set to true, an RMI registry protected by SSL will be created and configured by the out-of-the-box management agent when the Java VM is started. If the `com.sun.management.jmxremote.registry.ssl` property is set to true, to have full security then `com.sun.management.jmxremote.ssl.need.client.auth` must also be enabled. Set appropriate paths to the `keystore` and `truststore` files. Set the passwords to the passwords set during keystore and truststore generation.

3. Restart Cassandra (page 176).

4. To run nodetool with SSL encryption, create a `cassandra/nodetool-ssl.properties` file in your home or client program directory with the following settings on the node on which nodetool will run.

For production:

```
-Dcom.sun.management.jmxremote.ssl=true
-Dcom.sun.management.jmxremote.ssl.need.client.auth=true
-Dcom.sun.management.jmxremote.registry.ssl=true
-Djavax.net.ssl.keyStore=/usr/local/lib/cassandra/conf/server-keystore.jks
-Djavax.net.ssl.keyStorePassword=myKeyPass
-Djavax.net.ssl.trustStore=/usr/local/lib/cassandra/conf/server-truststore.jks
-Djavax.net.ssl.trustStorePassword=truststorePass
```

For development:

```
-Djavax.net.ssl.keyStore=keystore.node0
-Djavax.net.ssl.keyStorePassword=cassandra
-Djavax.net.ssl.trustStore=truststore.node0
-Djavax.net.ssl.trustStorePassword=cassandra
-Dcom.sun.management.jmxremote.ssl.need.client.auth=true
-Dcom.sun.management.jmxremote.registry.ssl=true
```

5. Start nodetool with the `--ssl` option for encrypted connection for any nodetool operation.

```
$ nodetool --ssl info ## Package installations
$ install_location/bin/nodetool --ssl info ## Tarball installations
```

6. Start nodetool with the `--ssl` option for encrypted connection and a username and password for authentication and authorization for any nodetool operation.
Using jconsole (JMX) with SSL encryption

Using jconsole with SSL requires the same JMX changes to cassandra-env.sh as nodetool. See using nodetool (JMX) with SSL encryption (page 149). There is no need to create nodetool-ssl.properties, but the same JVM keystore and truststore options must be specified with jconsole on the command line.

The location of the cassandra-env.sh file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td>/etc/dse/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Installations</td>
<td></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball</td>

Prerequisites: Prepare SSL certificates with a self-signed CA (page 134) for production, or prepare SSL certificates (page 133) for development. Additionally, configure client-to-node encryption (page 146).

1. Copy the keystore and truststore files created in the prerequisite to the node where jconsole will be run. In this example, the files are server-keystore.jks and server-truststore.jks.

2. Run jconsole using the JVM options:

   ```
   jconsole -J-Djavax.net.ssl.keyStore=server-keystore.jks
   -J-Djavax.net.ssl.keyStorePassword=myKeyPass
   -J-Djavax.net.ssl.trustStore=server-truststore.jks
   -J-Djavax.net.ssl.trustStorePassword=truststorePass
   ```

   If no errors occur, jconsole will start. If connecting to a remote node, enter the hostname and JMX port, in Remote Process. If using authentication, enter the username and password.

Configuring firewall port access

The following ports must be open to allow bi-directional communication between nodes, including certain Cassandra ports. Configure the firewall running on nodes in your Cassandra cluster accordingly. Without open ports as shown, nodes will act as a standalone database server and will not join the Cassandra cluster.
### Table 4: Public port

<table>
<thead>
<tr>
<th>Port number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>22</td>
<td>SSH port</td>
</tr>
</tbody>
</table>

### Table 5: Cassandra inter-node ports

<table>
<thead>
<tr>
<th>Port number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7000</td>
<td>Cassandra inter-node cluster communication.</td>
</tr>
<tr>
<td>7001</td>
<td>Cassandra SSL inter-node cluster communication.</td>
</tr>
<tr>
<td>7199</td>
<td>Cassandra JMX monitoring port.</td>
</tr>
</tbody>
</table>

### Table 6: Cassandra client ports

<table>
<thead>
<tr>
<th>Port number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9042</td>
<td>Cassandra client port.</td>
</tr>
<tr>
<td>9160</td>
<td>Cassandra client port (Thrift).</td>
</tr>
<tr>
<td>9142</td>
<td>Default for native_transport_port_ssl (page 106), useful when both encrypted and unencrypted connections are required</td>
</tr>
</tbody>
</table>

### Configuring gossip settings

When a node first starts up, it looks at its cassandra.yaml configuration file to determine the name of the Cassandra cluster it belongs to; which nodes (called seeds) to contact to obtain information about the other nodes in the cluster; and other parameters for determining port and range information.

The location of the cassandra.yaml file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

1. In the cassandra.yaml file, set the following parameters:

### Configuring the heap dump directory

Analyzing the heap dump file can help troubleshoot memory problems. Cassandra starts Java with the option `-XX:+HeapDumpOnOutOfMemoryError`. Using this option triggers a heap dump in the event of an out-of-memory condition. The heap dump file consists of references to objects that cause the heap to overflow. By default, Cassandra puts the file in a subdirectory
Configuration

of the working, root directory when running as a service. If Cassandra does not have write permission to the root directory, the heap dump fails. If the root directory is too small to accommodate the heap dump, the server crashes.

To ensure that a heap dump succeeds and to prevent crashes, configure a heap dump directory that is:

- Accessible to Cassandra for writing
- Large enough to accommodate a heap dump

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra-env.sh</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra-env.sh</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra-env.sh</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/conf/cassandra-env.sh</code></td>
</tr>
</tbody>
</table>

Base the size of the directory on the value of the Java `-mx` option.

Set the location of the heap dump in the `cassandra-env.sh` file.

1. Open the `cassandra-env.sh` file for editing.

2. Scroll down to the comment about the heap dump path:

   ```bash
   # set jvm HeapDumpPath with CASSANDRA_HEAPDUMP_DIR
   if [ "x$CASSANDRA_HEAPDUMP_DIR" != "x" ]; then
     JVM_OPTS="$JVM_OPTS -XX:HeapDumpPath=$CASSANDRA_HEAPDUMP_DIR/
     cassandra-`date +%s`-pid$$hprof"
   fi
   ```

3. On the line after the comment, set the `CASSANDRA_HEAPDUMP_DIR` to the path you want to use:

   ```bash
   # set jvm HeapDumpPath with CASSANDRA_HEAPDUMP_DIR
   export CASSANDRA_HEAPDUMP_DIR=path
   if [ "x$CASSANDRA_HEAPDUMP_DIR" != "x" ]; then
     JVM_OPTS="$JVM_OPTS -XX:HeapDumpPath=$CASSANDRA_HEAPDUMP_DIR/
     cassandra-`date +%s`-pid$$hprof"
   fi
   ```
4. Save the `cassandra-env.sh` file and restart.

**Configuring virtual nodes**

**Enabling virtual nodes on a new cluster**

Generally when all nodes have equal hardware capability, they should have the same number of virtual nodes (vnodes). If the hardware capabilities vary among the nodes in your cluster, assign a proportional number of vnodes to the larger machines. For example, you could designate your older machines to use 128 vnodes and your new machines (that are twice as powerful) with 256 vnodes.

The location of the `cassandra.yaml` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
</tbody>
</table>

1. Set the number of tokens on each node in your cluster with the `num_tokens` parameter in the `cassandra.yaml` file.

   The recommended value is 256. Do not set the `initial_token` parameter.

**Related information:**

| Install locations | [Install location topics](page 85) |

**Enabling virtual nodes on an existing production cluster**

You cannot directly convert a single-token nodes to a vnode. However, you can configure another datacenter configured with vnodes already enabled and let Cassandra automatic mechanisms distribute the existing data into the new nodes. This method has the least impact on performance.

1. **Add a new datacenter to the cluster** *(page 180).*

2. Once the new datacenter with vnodes enabled is up, switch your clients to use the new datacenter.

3. Run a full repair with `nodetool repair` *(page 311).*
Configuration

This step ensures that after you move the client to the new datacenter that any previous writes are added to the new datacenter and that nothing else, such as hints, is dropped when you remove the old datacenter.

4. Update your schema to no longer reference the old datacenter.

5. Remove the old datacenter from the cluster.

See Decommissioning a datacenter (page 191).

Using multiple network interfaces

How to configure Cassandra for multiple network interfaces or when using different regions in cloud implementations.

You must configure settings in both the cassandra.yaml file and the property file (cassandra-rackdc.properties or cassandra-topology.properties) used by the snitch.

Configuring cassandra.yaml for multiple networks or across regions in cloud implementations

In multiple networks or cross-region cloud scenarios, communication between datacenters can only take place using an external IP address. The external IP address is defined in the cassandra.yaml file using the broadcast_address setting. Configure each node as follows:

1. In the cassandra.yaml, set the listen_address (page 87) to the private IP address of the node, and the broadcast_address (page 100) to the public address of the node.

   This allows Cassandra nodes to bind to nodes in another network or region, thus enabling multiple data-center support. For intra-network or region traffic, Cassandra switches to the private IP after establishing a connection.

2. Set the addresses of the seed nodes in the cassandra.yaml file to that of the public IP. Private IP are not routable between networks. For example:

   ```
   seeds: 50.34.16.33, 60.247.70.52
   ```

   **Note:** Do not make all nodes seeds, see Internode communications (gossip) (page 21).

3. Be sure that the storage_port (page 102) or ssl_storage_port (page 116) is open on the public IP firewall.
Caution: Be sure to enable encryption and authentication when using public IPs. See Node-to-node encryption (page 144). Another option is to use a custom VPN to have local, inter-region/datacenter IPs.

Additional cassandra.yaml configuration for non-EC2 implementations

If multiple network interfaces are used in a non-EC2 implementation, enable the listen_on_broadcast_address option.

listen_on_broadcast_address: true

In non-EC2 environments, the public address to private address routing is not automatically enabled. Enabling listen_on_broadcast_address allows Cassandra to listen on both listen_address and broadcast_address with two network interfaces.

Configuring the snitch for multiple networks

External communication between the datacenters can only happen when using the broadcast_address (public IP).

The GossipingPropertyFileSnitch (page 31) is recommended for production. The cassandra-rackdc.properties file defines the datacenters used by this snitch. Enable the option prefer_local to ensure that traffic to broadcast_address will re-route to listen_address.

For each node in the network, specify its datacenter in cassandra-rackdc.properties file.

In the example below, there are two cassandra datacenters and each datacenter is named for its workload. The datacenter naming convention in this example is based on the workload. You can use other conventions, such as DC1, DC2 or 100, 200. (datacenter names are case-sensitive.)
### Network A

<table>
<thead>
<tr>
<th>Node and datacenter:</th>
<th>Network B</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>node0</strong></td>
<td>• <strong>node0</strong></td>
</tr>
<tr>
<td>dc=DC_A_cassandra</td>
<td>dc=DC_A_cassandra</td>
</tr>
<tr>
<td>rack=RAC1</td>
<td>rack=RAC1</td>
</tr>
<tr>
<td>• <strong>node1</strong></td>
<td>• <strong>node1</strong></td>
</tr>
<tr>
<td>dc=DC_A_cassandra</td>
<td>dc=DC_A_cassandra</td>
</tr>
<tr>
<td>rack=RAC1</td>
<td>rack=RAC1</td>
</tr>
<tr>
<td>• <strong>node2</strong></td>
<td>• <strong>node2</strong></td>
</tr>
<tr>
<td>dc=DC_B_cassandra</td>
<td>dc=DC_B_cassandra</td>
</tr>
<tr>
<td>rack=RAC1</td>
<td>rack=RAC1</td>
</tr>
<tr>
<td>• <strong>node3</strong></td>
<td>• <strong>node3</strong></td>
</tr>
<tr>
<td>dc=DC_B_cassandra</td>
<td>dc=DC_B_cassandra</td>
</tr>
<tr>
<td>rack=RAC1</td>
<td>rack=RAC1</td>
</tr>
<tr>
<td>• <strong>node4</strong></td>
<td>• <strong>node4</strong></td>
</tr>
<tr>
<td>dc=DC_A_analytics</td>
<td>dc=DC_A_analytics</td>
</tr>
<tr>
<td>rack=RAC1</td>
<td>rack=RAC1</td>
</tr>
<tr>
<td>• <strong>node5</strong></td>
<td>• <strong>node5</strong></td>
</tr>
<tr>
<td>dc=DC_A_search</td>
<td>dc=DC_A_search</td>
</tr>
<tr>
<td>rack=RAC1</td>
<td>rack=RAC1</td>
</tr>
</tbody>
</table>

### Configuring the snitch for cross-region communication in cloud implementations

**Note:** Be sure to use the appropriate snitch (page 28) for your implementation. If deploying on Amazon EC2, see the instructions in Ec2MultiRegionSnitch (page 33).

In cloud deployments, the region name is treated as the datacenter name and availability zones are treated as racks within a datacenter. For example, if a node is in the **us-east-1** region, **us-east** is the datacenter name and **1** is the rack location. (Racks are important for distributing replicas, but not for datacenter naming.)

In the example below, there are two cassandra datacenters and each datacenter is named for its workload. The datacenter naming convention in this example is based on the workload. You can use other conventions, such as DC1, DC2 or 100, 200. (datacenter names are case-sensitive.)

For each node, specify its datacenter in the cassandra-rackdc.properties. The **dc_suffix** option defines the datacenters used by the snitch. Any other lines are ignored.
<table>
<thead>
<tr>
<th>Region: us-east</th>
<th>Region: us-west</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Node and datacenter:</strong></td>
<td><strong>Node and datacenter:</strong></td>
</tr>
<tr>
<td>• node0</td>
<td>• node0</td>
</tr>
<tr>
<td>dc_suffix=_1_cassandra</td>
<td>dc_suffix=_1_cassandra</td>
</tr>
<tr>
<td>• node1</td>
<td>• node1</td>
</tr>
<tr>
<td>dc_suffix=_1_cassandra</td>
<td>dc_suffix=_1_cassandra</td>
</tr>
<tr>
<td>• node2</td>
<td>• node2</td>
</tr>
<tr>
<td>dc_suffix=_2_cassandra</td>
<td>dc_suffix=_2_cassandra</td>
</tr>
<tr>
<td>• node3</td>
<td>• node3</td>
</tr>
<tr>
<td>dc_suffix=_2_cassandra</td>
<td>dc_suffix=_2_cassandra</td>
</tr>
<tr>
<td>• node4</td>
<td>• node4</td>
</tr>
<tr>
<td>dc_suffix=_1_analytics</td>
<td>dc_suffix=_1_analytics</td>
</tr>
<tr>
<td>• node5</td>
<td>• node5</td>
</tr>
<tr>
<td>dc_suffix=_1_search</td>
<td>dc_suffix=_1_search</td>
</tr>
</tbody>
</table>

This results in four **us-east** datacenters:

- us-east_1_cassandra
- us-east_2_cassandra
- us-east_1_analytics
- us-east_1_search

This results in four **us-west** datacenters:

- us-west_1_cassandra
- us-west_2_cassandra
- us-west_1_analytics
- us-west_1_search

The location of the **cassandra.yaml** file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

The location of the **cassandra-rackdc.properties** file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-rackdc.properties</td>
</tr>
</tbody>
</table>
### Configuration

**Cassandra package installations**

/etc/cassandra/cassandra-rackdc.properties

**Cassandra tarball installations**

install_location/conf/cassandra-rackdc.properties

The location of the `cassandra-topology.properties` file depends on the type of installation:

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>
<th>/etc/dse/cassandra/cassandra-topology.properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-topology.properties</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-topology.properties</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-topology.properties</td>
</tr>
</tbody>
</table>

### Configuring logging

Cassandra provides logging functionality using Simple Logging Facade for Java (SLF4J) with a logback backend. Logs are written to the system.log and debug.log in the Cassandra logging directory. You can configure logging programmatically or manually. Manual ways to configure logging are:

- Run the `nodetool setlogginglevel` (*page 328*) command.
- Configure the `logback-test.xml` or `logback.xml` file installed with Cassandra.
- Use the JConsole (*page 226*) tool to configure logging through JMX.

Logback looks for `logback-test.xml` first, and then for `logback.xml` file.

The location of the `logback.xml` file depends on the type of installation:

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>
<th>/etc/dse/cassandra/logback.xml</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/logback.xml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/logback.xml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/logback.xml</td>
</tr>
</tbody>
</table>

The XML configuration files looks like this:

```xml
<configuration scan="true">
  <jmxConfigurator />
  <appender name="FILE" class="ch.qos.logback.core.rolling.RollingFileAppender">
```
The appender configurations specify where to print the log and its configuration. The first appender directs logs to a file. The second appender directs logs to the console. You can change the following logging functionality:

- Rolling policy
  - The policy for rolling logs over to an archive
  - Location and name of the log file
  - Location and name of the archive
  - Minimum and maximum file size to trigger rolling

- Format of the message
- The log level
Log levels

The valid values for setting the log level include ALL for logging information at all levels, TRACE through ERROR, and OFF for no logging. TRACE creates the most verbose log, and ERROR, the least.

- ALL
- TRACE
- DEBUG
- INFO (Default)
- WARN
- ERROR
- OFF

**Note:** Increasing logging levels can generate heavy logging output on a moderately trafficked cluster.

You can use the `nodetool getlogginglevels` command to see the current logging configuration.

```
$ bin\nodetool getlogginglevels
Logger Name                  Log Level
ROOT                         INFO
com.thinkaurelius.thrift    ERROR
```

To add debug logging to a class permanently using the logback framework, use `nodetool setlogginglevel` to check you have the right class before you set it in the logback.xml file in `install_location/conf`. Modify to include the following line or similar at the end of the file:

```
<logger name="org.apache.cassandra.gms.FailureDetector" level="DEBUG"/>
```

Restart the node to invoke the change.

Migrating to logback from log4j

If you upgrade from a previous version of Cassandra that used log4j, you can convert `log4j.properties` files to `logback.xml` using the logback `PropertiesTranslator` web-application.

Using log file rotation

The default policy rolls the `system.log` file after the size exceeds 20MB. Archives are compressed in zip format. Logback names the log files `system.log.1.zip`, `system.log.2.zip`, and so on. For more information, see logback documentation.
Enabling extended compaction logging

You can configure Cassandra to collect in-depth information about compaction activity on a node, and write it to a dedicated log file. For details, see Enabling extended compaction logging (page 169).

Commit log archive configuration

Cassandra provides commit log archiving and point-in-time recovery. The commit log is archived at node startup and when a commit log is written to disk, or at a specified point-in-time. You configure this feature in the commitlog_archiving.properties configuration file.

The location of the commitlog_archiving.properties (page 169) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services</td>
<td>/etc/dse/cassandra/commitlog_archiving.properties</td>
</tr>
<tr>
<td>and package installations</td>
<td></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services</td>
<td>install_location/resources/cassandra/conf</td>
</tr>
<tr>
<td>and tarball installations</td>
<td></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/commitlog_archiving.properties</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/commitlog_archiving.properties</td>
</tr>
</tbody>
</table>

The commands archive_command and restore_command expect only a single command with arguments. The parameters must be entered verbatim. STDOUT and STDIN or multiple commands cannot be executed. To workaround, you can script multiple commands and add a pointer to this file. To disable a command, leave it blank.

- Archive a commit log segment:

<table>
<thead>
<tr>
<th>Command</th>
<th>archive_command=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameters</td>
<td>%path</td>
</tr>
<tr>
<td></td>
<td>%name</td>
</tr>
<tr>
<td>Example</td>
<td>archive_command=/bin/ln %path /backup/%name</td>
</tr>
</tbody>
</table>

- Restore an archived commit log:

<table>
<thead>
<tr>
<th>Command</th>
<th>restore_command=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameters</td>
<td>%from</td>
</tr>
</tbody>
</table>

Apache Cassandra 3.0 for DSE 5.0 (Earlier version)
Configuration

<table>
<thead>
<tr>
<th>Command</th>
<th>restore_command=</th>
</tr>
</thead>
<tbody>
<tr>
<td>%to</td>
<td>Name of live commit log directory.</td>
</tr>
</tbody>
</table>

Example

```
restore_command=cp -f %from %to
```

- Set the restore directory location:

<table>
<thead>
<tr>
<th>Command</th>
<th>restore_directories=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format</td>
<td>restore_directories=restore_directory_location</td>
</tr>
</tbody>
</table>

- Restore mutations created up to and including the specified timestamp:

<table>
<thead>
<tr>
<th>Command</th>
<th>restore_point_in_time=</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format</td>
<td>&lt;timestamp&gt; (YYYY:MM:DD HH:MM:SS)</td>
</tr>
<tr>
<td>Example</td>
<td>restore_point_in_time=2013:12:11 17:00:00</td>
</tr>
</tbody>
</table>

Restore stops when the first client-supplied timestamp is greater than the restore point timestamp. Because the order in which Cassandra receives mutations does not strictly follow the timestamp order, this can leave some mutations unrecovered.

Generating tokens

If not using virtual nodes (vnodes), you must calculate tokens for your cluster.

The following topics in the Cassandra 1.1 documentation provide conceptual information about tokens:

- Data Distribution in the Ring (page )
- Replication Strategy (page )

About calculating tokens for single or multiple datacenters in Cassandra 1.2 and later:

- Single datacenter deployments: calculate tokens by dividing the hash range by the number of nodes in the cluster.
- Multiple datacenter deployments: calculate the tokens for each datacenter so that the hash range is evenly divided for the nodes in each datacenter.

For more explanation, see be sure to read the conceptual information mentioned above.

The method used for calculating tokens depends on the type of partitioner:
Calculating tokens for the Murmur3Partitioner

Use this method for generating tokens when you are **not** using virtual nodes (vnodes) and using the Murmur3Partitioner (page 27) (default). This partitioner uses a maximum possible range of hash values from $-2^{63}$ to $+2^{63}-1$. To calculate tokens for this partitioner:

```python
python -c "print [str(((2**64 / number_of_tokens) * i) - 2**63) for i in range(number_of_tokens)]"
```

For example, to generate tokens for 6 nodes:

```python
python -c "print [str(((2**64 / 6) * i) - 2**63) for i in range(6)]"
```

The command displays the token for each node:

```python
[ '-9223372036854775808', '-6148914691236517206', '-3074457345618258604', '-2', '3074457345618258600', '6148914691236517202' ]
```

Calculating tokens for the RandomPartitioner

To calculate tokens when using the RandomPartitioner (page 27) in Cassandra 1.2 clusters, use the Cassandra 1.1 Token Generating Tool (page 27).

**Hadoop support**

Cassandra support for integrating Hadoop with Cassandra includes:

- MapReduce

  **Notice:** Apache Pig is no longer supported as of Cassandra 3.0.

You can use Cassandra 3.0 with Hadoop 2.x or 1.x with some restrictions:

- You must run separate datacenters: one or more datacenters with nodes running just Cassandra (for Online Transaction Processing) and others with nodes running C* & with Hadoop installed. See Isolate Cassandra and Hadoop (page 167) for details.

- Before starting the datacenters of Cassandra/Hadoop nodes, disable virtual nodes (vnodes).

  **Note:** You only need to disable vnodes in datacenters with nodes running Cassandra AND Hadoop.

To disable virtual nodes:

1. In the cassandra.yaml file, set num_tokens to 1.

2. Uncomment the initial_token property and set it to 1 or to the value of a generated token for a multi-node cluster.

3. Start the cluster for the first time.
You cannot convert single-token nodes to vnodes. See Enabling virtual nodes on an existing production cluster (page 155) for another option.

Setup and configuration, involves overlaying a Hadoop cluster on Cassandra nodes, configuring a separate server for the Hadoop NameNode/JobTracker, and installing a Hadoop TaskTracker and Data Node on each Cassandra node. The nodes in the Cassandra datacenter can draw from data in the HDFS Data Node as well as from Cassandra. The Job Tracker/Resource Manager (JT/RM) receives MapReduce input from the client application. The JT/RM sends a MapReduce job request to the Task Trackers/Node Managers (TT/NM) and an optional clients MapReduce. The data is written to Cassandra and results sent back to the client.

The Apache docs also cover how to get configuration and integration support.

Input and Output Formats

Hadoop jobs can receive data from CQL tables and indexes and can write their output to Cassandra tables as well as to the Hadoop File System. Cassandra 3.0 supports the following formats for these tasks:

- **CqlInputFormat** class: for importing job input into the Hadoop filesystem from CQL tables
- **CqlOutputFormat** class: for writing job output from the Hadoop filesystem to CQL tables
- **CqlBulkOutputFormat** class: generates Cassandra SSTables from the output of Hadoop jobs, then loads them into the cluster using the **SSTableLoaderBulkOutputFormat** class

Reduce tasks can store keys (and corresponding bound variable values) as CQL rows (and respective columns) in a given CQL table.

Running the wordcount example

Wordcount example JARs are located in the examples directory of the Cassandra source code installation. There are CQL and legacy examples in the hadoop_cql3_word_count
Configuration

and hadoop_word_count subdirectories, respectively. Follow instructions in the readme files.

Isolating Hadoop and Cassandra workloads

When you create a keyspace using CQL, Cassandra creates a virtual datacenter for a cluster, even a one-node cluster, automatically. You assign nodes that run the same type of workload to the same datacenter. The separate, virtual datacenters for different types of nodes segregate workloads running Hadoop from those running Cassandra. Segregating workloads ensures that only one type of workload is active per datacenter. Separating nodes running a sequential data load, from nodes running any other type of workload, such as Cassandra real-time OLTP queries is a best practice.

The location of the cassandra.yaml (page ) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>

Initializing a cluster

Initializing a multiple node cluster (single datacenter)

This topic contains information for deploying a Cassandra cluster with a single datacenter. If you're new to Cassandra, and haven't set up a cluster, see Planning and testing cluster deployments (page ).

Prerequisites: Each node must be correctly configured before starting the cluster. You must determine or perform the following before starting the cluster:

- A good understanding of how Cassandra works. At minimum, be sure to read Understanding the architecture (page 18), especially the Data replication section, and Cassandra's rack feature (page ).
- Install Cassandra on each node.
- Choose a name for the cluster.
- Get the IP address of each node.
- Determine which nodes will be seed nodes. Do not make all nodes seed nodes. Please read Internode communications (gossip) (page 21).
- Determine the snitch (page 28) and replication strategy (page 22). The GossipingPropertyFileSnitch (page 31) and NetworkTopologyStrategy (page 22) are recommended for production environments.
- Determine a naming convention for each rack. For example, good names are RAC1, RAC2 or R101, R102.
- The cassandra.yaml (page 86) configuration file, and property files such as cassandra-rackdc.properties, give you more configuration options. See the Configuration section (page 86) for more information.

This example describes installing a 6 node cluster spanning 2 racks in a single datacenter. Each node is already configured to use the GossipingPropertyFileSnitch (page 31) and 256 virtual nodes (vnodes).

In Cassandra, "datacenter" is synonymous with "replication group". Both terms refer to a set of nodes configured as a group for replication purposes.

1. Suppose you install Cassandra on these nodes:

```
node0 110.82.155.0 (seed1)
node1 110.82.155.1
node2 110.82.155.2
node3 110.82.156.3 (seed2)
node4 110.82.156.4
node5 110.82.156.5
```
Note: It is a best practice to have more than one seed node per datacenter.

2. If you have a firewall running in your cluster, you must open certain ports for communication between the nodes. See Configuring firewall port access (page 152).

3. If Cassandra is running, you must stop the server and clear the data:

   Doing this removes the default cluster_name (Test Cluster) from the system table. All nodes must use the same cluster name.

   Package installations:
   
   a. Stop Cassandra:

```
$ sudo service dse stop #Stops DataStax Enterprise
```

   b. Clear the data:

```
$ sudo rm -rf /var/lib/cassandra/data/system/*
```

   Tarball installations:
   
   a. Stop Cassandra:

```
$ ps auwx | grep dse #Stops DataStax Enterprise
$ sudo kill pid
```

   b. Clear the data:

```
$ sudo rm -rf /var/lib/cassandra/data/data/system/*
```

4. Set the properties in the cassandra.yaml file for each node:

   Note: After making any changes in the cassandra.yaml file, you must restart the node for the changes to take effect.

   Properties to set:
   
   • cluster_name:
   • num_tokens: recommended value: 256
   • -seeds: internal IP address of each seed node

   In new clusters. Seed nodes don't perform bootstrap (page ) (the process of a new node joining an existing cluster.)

   • listen_address:
Initializing a cluster

If the node is a seed node, this address must match an IP address in the seeds list. Otherwise, gossip communication fails because it doesn't know that it is a seed.

If not set, Cassandra asks the system for the local address, the one associated with its hostname. In some cases Cassandra doesn't produce the correct address and you must specify the listen_address.

- **rpc_address**: listen address for client connections
- **endpoint_snitch**: name of snitch (See endpoint_snitch (page 90).) If you are changing snitches, see Switching snitches (page 192).
- **auto_bootstrap**: false (Add this setting only when initializing a clean node with no data.)

**Note**: If the nodes in the cluster are identical in terms of disk layout, shared libraries, and so on, you can use the same cassandra.yaml file on all of them.

Example:

```yaml
cluster_name: 'MyCassandraCluster'
um_tokens: 256
seed_provider:
  - class_name: org.apache.cassandra.locator.SimpleSeedProvider
    parameters:
      - seeds: "110.82.155.0,110.82.155.3"
listen_address:
rpc_address: 0.0.0.0
endpoint_snitch: GossipingPropertyFileSnitch
```

If rpc_address is set to a wildcard address (0.0.0.0), then broadcast_rpc_address must be set, or the service won't even start.

5. In the cassandra-rackdc.properties file, assign the datacenter and rack names you determined in the Prerequisites. For example:

   ```
   # indicate the rack and dc for this node
dc=DC1
rack=RAC1
   ```

6. The GossipingPropertyFileSnitch always loads cassandra-topology.properties when that file is present. Remove the file from each node on any new cluster or any cluster migrated from the PropertyFileSnitch.

7. After you have installed and configured Cassandra on all nodes, DataStax recommends starting the seed nodes one at a time, and then starting the rest of the nodes.
Note: If the node has restarted because of automatic restart, you must first stop the node and clear the data directories, as described above (page 169).

Package installations:

$ sudo service dse start #Starts DataStax Enterprise

Tarball installations:

$ cd install_location
$ bin/dse cassandra #Starts DataStax Enterprise

8. To check that the ring is up and running, run:

Package installations:

$ nodetool status

Tarball installations:

$ cd install_location
$ bin/nodetool status

The output should list each node, and show its status as UN (Up Normal).

The location of the cassandra.yaml (page ) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

Related information:
Initializing a cluster

Install locations [Install location topics.] (page 85)

Initializing a multiple node cluster (multiple datacenters)

This topic contains information for deploying a Cassandra cluster with multiple datacenters. If you're new to Cassandra, and haven't set up a cluster, see Planning and testing cluster deployments (page 85).

This example describes installing a six node cluster spanning two datacenters. Each node is configured to use the GossipingPropertyFileSnitch (page 31) (multiple rack aware) and 256 virtual nodes (vnodes).

In Cassandra, "datacenter" is synonymous with "replication group". Both terms refer to a set of nodes configured as a group for replication purposes.

Prerequisites: Each node must be correctly configured before starting the cluster. You must determine or perform the following before starting the cluster:

- A good understanding of how Cassandra works. At minimum, be sure to read Understanding the architecture (page 18) (especially the Data replication (page 25) section) and the rack feature of Cassandra (page 31).
- Install Cassandra on each node.
- Choose a name for the cluster.
- Get the IP address of each node.
- Determine which nodes will be seed nodes. Do not make all nodes seed nodes. Please read Internode communications (gossip) (page 21).
- Determine the snitch (page 28) and replication strategy (page 22). The GossipingPropertyFileSnitch (page 31) and NetworkTopologyStrategy (page 22) are recommended for production environments.
- Determine a naming convention for each datacenter and rack. Examples: DC1, DC2 or 100, 200 / RAC1, RAC2 or R101, R102. Choose the name carefully; renaming a datacenter is not possible.
- The The cassandra.yml configuration file (page 86), and property files such as cassandra-rackdc.properties, give you more configuration options. See the Configuration section (page 86) for more information.

1. Suppose you install Cassandra on these nodes:

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>node0</td>
<td>10.168.66.41 (seed1)</td>
</tr>
<tr>
<td>node1</td>
<td>10.176.43.66</td>
</tr>
<tr>
<td>node2</td>
<td>10.168.247.41</td>
</tr>
<tr>
<td>node3</td>
<td>10.176.170.59 (seed2)</td>
</tr>
<tr>
<td>node4</td>
<td>10.169.61.170</td>
</tr>
<tr>
<td>node5</td>
<td>10.169.30.138</td>
</tr>
</tbody>
</table>

Note: It is a best practice to have more than one seed node per datacenter.
2. If you have a firewall running in your cluster, you must open certain ports for communication between the nodes. See Configuring firewall port access (page 152).

3. If Cassandra is running, you must stop the server and clear the data:

   Doing this removes the default cluster_name (Test Cluster) from the system table. All nodes must use the same cluster name.

   **Package installations:**

   a. Stop Cassandra:

   ```bash
   $ sudo service dse stop #Stops DataStax Enterprise
   ```

   b. Clear the data:

   ```bash
   $ sudo rm -rf /var/lib/cassandra/data/system/*
   ```

   **Tarball installations:**

   a. Stop Cassandra:

   ```bash
   $ ps auwx | grep dse #Stops DataStax Enterprise
   $ sudo kill pid
   ```

   b. Clear the data:

   ```bash
   $ sudo rm -rf /var/lib/cassandra/data/data/system/*
   ```

4. Set the properties in the cassandra.yaml file for each node:

   **Note:** After making any changes in the cassandra.yaml file, you must restart the node for the changes to take effect.

   **Properties to set:**

   - **cluster_name:**
   - **num_tokens:** recommended value: 256
   - **-seeds:** internal IP address of each seed node

   In new clusters. Seed nodes don’t perform bootstrap (page 152) (the process of a new node joining an existing cluster.)

   - **listen_address:**
Initializing a cluster

If the node is a seed node, this address must match an IP address in the seeds list. Otherwise, gossip communication fails because it doesn't know that it is a seed.

If not set, Cassandra asks the system for the local address, the one associated with its hostname. In some cases Cassandra doesn't produce the correct address and you must specify the listen_address.

- **rpc_address**: listen address for client connections
- **endpoint_snitch**: name of snitch (See endpoint_snitch (page 90).) If you are changing snitches, see Switching snitches (page 192).
- **auto_bootstrap**: false (Add this setting only when initializing a clean node with no data.)

**Note**: If the nodes in the cluster are identical in terms of disk layout, shared libraries, and so on, you can use the same cassandra.yaml file on all of them.

Example:

```yaml
cluster_name: 'MyCassandraCluster'
num_tokens: 256
seed_provider:
  - class_name: org.apache.cassandra.locator.SimpleSeedProvider
    parameters:
      - seeds: "10.168.66.41,10.176.170.59"
listen_address: endpoint_snitch: GossipingPropertyFileSnitch

**Note**: Include at least one node from each datacenter in the seeds list.

5. In the cassandra-rackdc.properties file, assign the datacenter and rack names you determined in the Prerequisites. For example:

**Nodes 0 to 2**

```yaml
## Indicate the rack and dc for this node
dc=DC1
rack=RAC1
```

**Nodes 3 to 5**

```yaml
## Indicate the rack and dc for this node
dc=DC2
rack=RAC1
```
6. The GossipingPropertyFileSnitch always loads cassandra-topology.properties when that file is present. Remove the file from each node on any new cluster or any cluster migrated from the PropertyFileSnitch.

7. After you have installed and configured Cassandra on all nodes, DataStax recommends starting the seed nodes one at a time, and then starting the rest of the nodes.

   Note: If the node has restarted because of automatic restart, you must first stop the node and clear the data directories, as described above (page 169).

   Package installations:

   $ sudo service dse start #Starts DataStax Enterprise

   Tarball installations:

   $ cd install_location
   $ bin/dse cassandra #Starts DataStax Enterprise

8. To check that the ring is up and running, run:

   Package installations:

   $ nodetool status

   Tarball installations:

   $ cd install_location
   $ bin/nodetool status

   The output should list each node, and show its status as UN (Up Normal).

   The location of the cassandra.yaml (page ) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
</tbody>
</table>
Starting and stopping Cassandra

Starting Cassandra as a service

Start the Cassandra Java server process for packaged installations.

Startup scripts are provided in the `/etc/init.d` directory. The service runs as the `cassandra` user.

You must have root or sudo permissions to start Cassandra as a service.

1. On initial start-up, each node must be started one at a time, starting with your seed nodes:

   $ sudo service dse start #Starts DataStax Enterprise

   On Enterprise Linux systems, the Cassandra service runs as a java process.

Starting Cassandra as a stand-alone process

Start the Cassandra Java server process for tarball installations.

On initial start-up, each node must be started one at a time, starting with your seed nodes.

- To start Cassandra in the background:

   $ cd install_location
   $ bin/dse cassandra #Starts DataStax Enterprise

- To start Cassandra in the foreground:

   $ cd install_location
   $ bin/dse cassandra -f #Starts DataStax Enterprise

Stopping Cassandra as a service

Stopping the Cassandra Java server process on packaged installations.

1. You must have root or sudo permissions to stop the Cassandra service:
$ sudo service dse stop #Stop DataStax Enterprise

**Stopping Cassandra as a stand-alone process**

Stop the Cassandra Java server process on tarball installations.

1. Find the Cassandra Java process ID (PID), and then kill the process using its PID number:

   $ ps auwx | grep dse
   $ sudo kill pid #Stop DataStax Enterprise

**Clearing the data as a service**

Remove all data from a package installation.

To clear the data from the `default` directories:

1. After stopping (page 176) the service, run the following command:

   $ sudo rm -rf /var/lib/cassandra/*

**Clearing the data as a stand-alone process**

Remove data from a tarball installation.

- To clear all data from the `default` directories, including the commitlog and saved_caches:
  1. Stop (page 177) the process.
  2. Run the following command from the install directory:

     $ cd install_location
     $ sudo rm -rf data/*

- To clear the only the data directory:
  1. Stop (page 177) the process.
  2. Run the following command from the install directory:

     $ cd install_location
     $ sudo rm -rf data/data/*
Operations

Adding or removing nodes, datacenters, or clusters

Adding nodes to an existing cluster

Virtual nodes (vnodes) greatly simplify adding nodes to an existing cluster:

- Calculating tokens and assigning them to each node is no longer required.
- Rebalancing a cluster is no longer necessary because a node joining the cluster assumes responsibility for an even portion of the data.

For a detailed explanation about how vnodes work, see Virtual nodes (page 23).

**Note:** If you do not use vnodes, see Adding single-token nodes to a cluster (page 197).

Be sure to use the same version of Cassandra on all nodes in the cluster. See Installing earlier releases of Apache Cassandra 3.0 (page 80).

1. Install Cassandra on the new nodes, but do not start Cassandra.

   If your Cassandra installation on Debian starts automatically, you must stop (page 176) the node and clear (page 177) the data.

2. Depending on the snitch used in the cluster, set either the properties in the cassandra-topology.properties or the cassandra-rackdc.properties file:

   - The **PropertyFileSnitch** (page 30) uses the cassandra-topology.properties file.
   - The **GossipingPropertyFileSnitch** (page 31), **Ec2Snitch** (page 32), **Ec2MultiRegionSnitch** (page 33), and **GoogleCloudSnitch** (page 36) use the cassandra-rackdc.properties file.

The location of the cassandra-topology.properties file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>File Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-topology.properties</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-topology.properties</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-topology.properties</td>
</tr>
</tbody>
</table>
### Cassandra tarball installations

<table>
<thead>
<tr>
<th>Install Location</th>
<th>File Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>install_location/conf/</td>
<td>cassandra-topology.properties</td>
</tr>
</tbody>
</table>

The location of the `cassandra-rackdc.properties` file depends on the type of installation:

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>
<th>/etc/dse/cassandra/cassandra-rackdc.properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-rackdc.properties</td>
</tr>
</tbody>
</table>

3. Set the following properties in the `cassandra.yaml` file:

**auto_bootstrap (page 99)**

- If this option has been set to false, you must set it to true. This option is not listed in the default `cassandra.yaml` configuration file and defaults to true.

**cluster_name (page 87)**

- The name of the cluster the new node is joining.

**listen_address (page 87)/broadcast_address (page 100)**

- Can usually be left blank. Otherwise, use IP address or host name that other Cassandra nodes use to connect to the new node.

**endpoint_snitch (page 28)**

- The snitch Cassandra uses for locating nodes and routing requests.

**num_tokens (page 100)**

- The number of vnodes to assign to the node. Use the same number of tokens as set on other nodes in the datacenter. Token ranges are proportionally distributed, if the hardware capabilities varies, assign more token ranges to the systems with higher capacity and better performance.

**allocate_tokens_for_local_replication_factor (page 101)**

- Specify the replication factor (RF) of the keyspaces in the datacenter. If you plan to increase the RF after adding the node, then use the (new) higher value. When the RF varies between keyspaces and you are adding a single node, use the highest RF value. When adding multiple nodes, use alternate between the most data intensive keyspace RFs. For example, in a datacenter with keyspace `cycling` RF=3, keyspace `hockey` RF=2, and keyspace `basketball` RF =1, set the first node you are adding to 3 and the second node to 2.

**seed_provider (page 92)**

- Make sure that the new node lists at least one node in the existing cluster. The `-seeds` list determines which nodes the new node should contact to learn about the cluster and establish the gossip process.
Note: Seed nodes cannot bootstrap (page ). Make sure the new node is not listed in the -seeds list. Do not make all nodes seed nodes. Please read Internode communications (gossip) (page 21).

Other non-default settings
Change any other non-default settings you have made to your existing cluster in the cassandra.yaml file and cassandra-topology.properties or cassandra-rackdc.properties files. Use the diff command to find and merge any differences between existing and new nodes.

The location of the cassandra.yaml (page ) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

4. Start the bootstrap node.

5. Use nodetool status (page 341) to verify that the node is fully bootstrapped and all other nodes are up (UN) and not in any other state.

6. After all new nodes are running, run nodetool cleanup (page 255) on each of the previously existing nodes to remove the keys that no longer belong to those nodes. Wait for cleanup to complete on one node before running nodetool cleanup on the next node.

Cleanup can be safely postponed for low-usage hours.

Related information:
Starting Cassandra as a service [Start the Cassandra Java server process for packaged installations.] (page 176)
Starting Cassandra as a stand-alone process [Start the Cassandra Java server process for tarball installations.] (page 176)
The nodetool utility [A list of the available commands for managing a cluster.] (page 250)
Install locations [Install location topics.] (page 85)

Adding a datacenter to a cluster
Steps for adding a datacenter to an existing cluster.

The location of the cassandra.yaml (page ) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
</tbody>
</table>
Prerequisites:

If the new datacenter will use existing nodes from another datacenter or cluster, ensure that old data won't interfere with the new cluster:

1. Decommission each node that will be added to the new datacenter. See Removing a node (page 191).

2. Completely remove the application directories. See Clearing the data as a stand-alone process (page 177) or Clearing the data as a service (page 177).

3. After removal, install Cassandra (page 80) or DataStax Enterprise (page 472) from scratch.

   1. To prevent the client from prematurely connecting to the new datacenter and to ensure that the consistency level (page 61) for reads or writes does not query the new datacenter:

      a. Make sure that the clients are configured to use the DCAwareRoundRobinPolicy.

      b. Make sure that the clients point to an existing datacenter, so they don't try to access the new datacenter, which may not have any data.

      c. If using a QUORUM consistency level, change to LOCAL QUORUM.

      d. If using the ONE consistency level, set to LOCAL ONE.

   See the programming instructions for your driver (page ).

   Warning: If client applications, including DSE Search and DSE Analytics, are not properly configured, they may connect to the new datacenter before the datacenter is ready. This results in connection exceptions, timeouts, and/or inconsistent data.

2. Configure the keyspace and create the new datacenter:

   a. Use ALTER KEYSPACE (page ) to use the NetworkTopologyStrategy (page 25) for the following keyspaces:
      - All user-created
      - system:system_distributed and system_traces
      - DataStax Enterprise:
# dse_perf, see Configuring Performance Service replication strategy (page )
# system_auth and dse_security, see Configuring system_auth and dse_security keyspace replication (page ).
# dse_leases, cfs, cfs_archive, dsefs, and HiveMetaStore, see Setting the replication factor for analytics keyspaces (page ).

- OpsCenter (if installed)

This step is required for multiple datacenter clusters because nodetool rebuild (10 (page 184)) requires a replica of these keyspaces in the specified source datacenter.

b. Ensure that the defined class for all datacenters is NetworkTopologyStrategy.

You can use cqlsh to create or alter a keyspace:

```
ALTER KEYSPACE "sample_ks" WITH REPLICAION =
{ 'class' : 'NetworkTopologyStrategy', 'ExistingDC' : 3 };
```

Note: Datacenter names are case sensitive. Verify the case of the using utility, such as dsetool status.

3. In the new datacenter, install Cassandra on each new node. Do not start the service or restart the node.
   Be sure to use the same version of Cassandra on all nodes in the cluster. See Installing earlier releases of Apache Cassandra 3.0 (page 80).

4. Configure cassandra.yaml on each new node following the configuration of the other nodes in the cluster:
   a. Set other cassandra.yaml properties, such as -seeds and endpoint_snitch, to match the settings in the cassandra.yaml files on other nodes in the cluster.
   Properties to set:
   - cluster_name:
   - num_tokens: recommended value: 256
   - -seeds: internal IP address of each seed node
   In new clusters. Seed nodes don’t perform bootstrap (page ) (the process of a new node joining an existing cluster.)
   - listen_address:
If the node is a seed node, this address must match an IP address in the seeds list. Otherwise, gossip communication fails because it doesn’t know that it is a seed.

If not set, Cassandra asks the system for the local address, the one associated with its hostname. In some cases Cassandra doesn’t produce the correct address and you must specify the listen_address.

- **rpc_address**: listen address for client connections
- **endpoint_snitch**: name of snitch (See endpoint_snitch (page 90).) If you are changing snitches, see Switching snitches (page 192).
- **auto_bootstrap**: false (Add this setting only when initializing a clean node with no data.)

**Note**: Do not make all nodes seeds, see Internode communications (gossip) (page 21).

b. Use the following settings to configure the vnode token allocation:

- **Random selection algorithm**: Set `num_tokens` (page 100) on each node. Comment out `initial_token` (page 100) and `allocate_tokens_for_local_replication_factor` (page 101).

  The `num_tokens` (page 100) recommended value is 256. The recommended settings for DataStax Enterprise varies depending on the system type, refer to the Guidelines for using virtual nodes (page )

  The `num_tokens` (page 100) recommended value is 8 and the `allocate_tokens_for_local_replication_factor` (page 101) is the either the highest replication factor of keyspaces in the datacenter or the RF of the most data intensive keypspace.

  **Note**: If using single-token architecture, see Generating tokens (page 164) and Adding or replacing single-token nodes (page 197).

5. On each new node, add the new datacenter definition to the properties file for the type of snitches (page 28) used in the cluster:

  **Note**: Do not use the SimpleSnitch. The SimpleSnitch (default) is used only for single-datacenter deployments. It does not recognize datacenter or rack information and can be used only for single-datacenter deployments or single-zone in public clouds.
Table 7: Configuration file per snitch

<table>
<thead>
<tr>
<th>Snitch</th>

</table>

6. In the existing datacenters:

   a. On some nodes, update the seeds property in the cassandra.yaml file to include the seed nodes in the new datacenter and restart those nodes. (Changes to the cassandra.yaml file require restarting to take effect.)

   b. Add the new datacenter definition to the properties file for the type of snitch used in the cluster (5 (page 183)). If changing snitches, see Switching snitches (page 192).

7. **Start Cassandra (page 176)** on one node on each rack.

8. Rotate starting Cassandra through the racks until all the nodes are up.

9. After all nodes are running in the cluster and the client applications are datacenter aware (1 (page 181)), use cqlsh to alter the keyspaces:

   ```
   ALTER KEYSPACE "sample_ks" WITH REPLICATION =
   {'class': 'NetworkTopologyStrategy', 'ExistingDC':3, 'NewDC':3};
   ```

   **Warning**: If client applications, including DSE Search and DSE Analytics, are not properly configured, they may connect to the new datacenter before the datacenter is ready. This results in connection exceptions, timeouts, and/or inconsistent data.

10. Run **nodetool rebuild (page 304)** on each node in the new datacenter.

    ```
    $ nodetool rebuild -- name_of_existing_data_center
    ```

    **Caution**: If you don’t specify the existing datacenter in the command line, the new nodes will appear to rebuild successfully, but will not contain any data.
If you miss this step, requests to the new datacenter with LOCAL_ONE or ONE consistency levels may fail if the existing datacenters are not completely in-sync.

This step ensures that the new nodes recognize the existing datacenters in the cluster.

You can run rebuild on one or more nodes at the same time. Run on one node at a time to reduce the impact on the existing cluster. Run on multiple nodes when the cluster can handle the extra I/O and network pressure.

The datacenters in the cluster are now replicating with each other.

The location of the `cassandra.yaml` file depends on the type of installation:

| DataStax Enterprise 5.0 Installer-Services and package installations | /etc/dse/cassandra/cassandra.yaml |
| DataStax Enterprise 5.0 Installer-No Services and tarball installations | `install_location/resources/cassandra/conf/cassandra.yaml` |
| Cassandra package installations | /etc/cassandra/cassandra.yaml |
| Cassandra tarball installations | `install_location/resources/cassandra/conf/cassandra.yaml` |

Related information:

- Starting Cassandra as a stand-alone process [Start the Cassandra Java server process for tarball installations.] (page 176)

Re replacing a dead node or dead seed node

Steps to replace a node that has died for some reason, such as hardware failure.

The procedure for replacing a dead node is the same for vnodes and single-token nodes. Extra steps are required for replacing dead seed nodes (page ).

1. Run nodetool status (page 341) to verify that the node is dead (DN).
2. Record the datacenter, address, and rack settings of the dead node; you will use these later.

3. Add the replacement node (page 80) to the network and record its IP address.

4. If the dead node was a seed node, change the cluster's seed node configuration on each node:
   
a. In the cassandra.yaml file for each node, remove the IP address of the dead node from the `seeds` list in the `seed-provider` (page 92) property.

   b. If the cluster needs a new seed node to replace the dead node, add the new node's IP address to the `seeds` list.

   **Attention:** In multiple data-center clusters, include at least one node from each datacenter (replication group) in the seed list. Designating more than a single seed node per datacenter is recommended for fault tolerance. Otherwise, gossip has to communicate with another datacenter when bootstrapping a node.

   Making every node a seed node is **not** recommended because of increased maintenance and reduced gossip performance. Gossip optimization is not critical, but it is recommended to use a small seed list (approximately three nodes per datacenter).

   c. Restart the node. (page 176)

5. On an existing node, gather setting information for the new node from the cassandra.yaml file:
   
   • `cluster_name`
   
   • `endpoint_snitch`
   
   • Other non-default settings: Use the diff tool to compare current settings with default settings.

6. Gather rack and datacenter information:
   
   • If the cluster uses the PropertyFileSnitch (page 30), record the rack and data assignments listed in the cassandra-topology.properties file, or copy the file to the new node.

   • If the cluster uses the GossipPropertyFileSnitch (page 31), Ec2Snitch (page 32), Ec2MultiRegionSnitch (page 33), or GoogleCloudSnitch (page 36), record the rack and datacenter assignments in the dead node's cassandra-rackdc.properties file.
7. Make sure that the new node meets all prerequisites and then Install Cassandra (page 80) on the new node, but do not start Cassandra.

   **Note**: Be sure to install the same version of Cassandra as is installed on the other nodes in the cluster. If not using the latest version, see Installing earlier releases of Apache Cassandra 3.0 (page 80).

8. If Cassandra automatically started on the node, stop (page 176) and clear (page 177) the data that was added automatically on startup.

9. Add values to the following properties in cassandara.yaml file from the information you gathered earlier:
   - `auto_bootstrap` (page 99): If this setting exists and is set to `false`, set it to `true`. (This setting is not included in the default cassandra.yaml configuration file.)
   - `cluster_name` (page 87)
   - `seed list` (page 92)

10. Add the rack and datacenter configuration:
    - If the cluster uses the GossipPropertyFileSnitch (page 31), Ec2Snitch (page 32), Ec2MultiRegionSnitch (page 33), or GoogleCloudSnitch (page 36):
      - **a.** Add the dead node's rack and datacenter assignments to the cassandra-rackdc.properties file on the replacement node.
        - **Note**: Do not remove the entry for the dead node’s IP address yet.
      - **b.** Delete the cassandra-topology.properties file.
    - If the cluster uses the PropertyFileSnitch (page 30):
      - **a.** Copy the cassandra-topology.properties file from an existing node, or add the settings to the local copy.
      - **b.** Edit the file to add an entry with the new node’s IP address and the dead node’s rack and datacenter assignments.

11. Start the new node with the replace_address (page 369) option, passing in the IP address of the dead node.

    Cassandra package installations:
    - **a.** Add the following option to cassandra-env.sh file:
      ```bash
      JVM_OPTS="$JVM_OPTS -Dcassandra.replace_address=address_of_dead_node"
      ```
b. Start the node *(page 176).*

c. After the node bootstraps, remove the `replace-address` parameter from `cassandra-env.sh`.

d. Restart the node *(page 176).*

Cassandra tarball installations:

- Start Cassandra with this option:
  
  ```
  $ sudo bin/cassandra -Dcassandra.replace_address=address_of_dead_node
  ```

12. Run `nodetool status` to verify that the new node has bootstrapped successfully.

13. In environments that use the PropertyFileSnitch, wait at least 72 hours and then remove the old node’s IP address from the `cassandra-topology.properties` file.

   This ensures that old node's information is removed from gossip. If removed from the property file too soon, problems may result. Use `nodetool gossipinfo (page 290)` to check the gossip status. The node is still in gossip until LEFT status disappears.

   **Note:** The `cassandra-rackdc.properties` file does not contain IP information; therefore this step is not required when using other snitches, such as GossipingPropertyFileSnitch.

The location of the `cassandra-topology.properties` file **depends on the type of installation**:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra-topology.properties</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra-topology.properties</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra-topology.properties</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/conf/cassandra-topology.properties</code></td>
</tr>
</tbody>
</table>

The location of the `cassandra.yaml` *(page...*) file **depends on the type of installation**:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>
</tr>

<tr>
<td>Cassandra tarball installations</td>
<td><code>/etc/cassandra/cassandra.yaml</code></td>
</tr>
</tbody>
</table>
Replacing a running node

Steps to replace a node with a new node, such as when updating to newer hardware or performing proactive maintenance.

You can replace a running node in two ways:

- Adding a node and then decommissioning the old node (page 189)
- Using nodetool to replace a running node (page 190)

**Note:** To change the IP address of a node, simply change the IP of node and then restart Cassandra. If you change the IP address of a seed node, you must update the `-seeds` parameter in the `seed_provider` (page 92) list in each node’s `cassandra.yaml` file.

The location of the `cassandra.yaml` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
</tbody>
</table>

Adding a node and then decommissioning the old node

You must prepare and start the replacement node, integrate it into the cluster, and then decommission the old node.

Be sure to use the same version of Cassandra on all nodes in the cluster. See Installing earlier releases of Apache Cassandra 3.0 (page 80).

1. Prepare and start the replacement node, as described in Adding nodes to an existing cluster (page 178).

   **Note:** If not using vnodes, see Adding single-token nodes to a cluster (page 197).

2. Confirm that the replacement node is alive:

   - Run `nodetool ring` (page 318) if not using vnodes.
   - Run `nodetool status` (page 341) if using vnodes.

The status should show:

- `nodetool ring: up`
Operations

- **nodetool status:** UN

3. Note the Host ID of the original node; it is used in the next step.

4. Using the Host ID of the original node, decommission the original node from the cluster using the **nodetool decommission** *(page 263)* command.

5. Run **nodetool cleanup** *(page 255)* on all the other nodes in the same datacenter.

**Using nodetool to replace a running node**

This method allows you to replace a running node while avoiding streaming the data twice or running cleanup.

**Caution:** If using a consistency level of ONE, you risk losing data because the node might contain the only copy of a record. Be absolutely sure that no application uses consistency level ONE.

1. Stop Cassandra *(page 176)* on the node to be replaced.

2. Follow the instructions for replacing a dead node *(page 185)* using the old node’s IP address for `-Dcassandra.replace_address`.

3. Ensure that consistency level *(page ) ONE is not used on this node.

**Related information:**
Removing a node *[Reduce the size of a datacenter.]* *(page 191)*

**Moving a node from one rack to another**

A common task is moving a node from one rack to another. For example, when using GossipPropertyFileSnitch, a common error is mistakenly placing a node in the wrong rack. To correct the error, use one of the following procedures.

- The preferred method is to decommission the node *(page 263)* and re-add it to the correct rack and datacenter.
  
  # This method takes longer to complete than the alternative method. Data is moved that the decommissioned node doesn't need anymore. Then the node gets new data while bootstrapping. The alternative method does both operations simultaneously.

- An alternative method is to update the node’s topology *(page 192)* and restart the node. Once the node is up, run a full repair *(page 215)* on the cluster.

  **Caution:** This method is not preferred because until the repair is completed, the node may blindly handle requests for data the node doesn't yet have. To mitigate this problem with request handling, start the node with `-Dcassandra.join_ring=false` after repairing once, then fully join the node to the cluster using the JMX method *(page 224)*.
org.apache.cassandra.db.StorageService.joinRing(). The node will be less likely to be out of sync with other nodes before it serves any requests. After joining the node to the cluster, repair the node again, so that any writes missed during the first repair will be captured.

**Decommissioning a datacenter**

Steps to properly remove a datacenter so no information is lost.

1. Make sure no clients are still writing to any nodes in the datacenter.

2. Run a full repair with `nodetool repair (page 311)`.
   
   This ensures that all data is propagated from the datacenter being decommissioned.

3. Change all keyspaces (page ) so they no longer reference the datacenter being removed.

4. Run `nodetool decommission (page 263)` on every node in the datacenter being removed.

**Removing a node**

Use these instructions when you want to remove nodes to reduce the size of your cluster, not for replacing a dead node (page 185).

**Attention:** If you are not using virtual nodes (page 23) (vnodes), you must rebalance the cluster.

- Check whether the node is up or down using `nodetool status (page 341)`:

  The nodetool command shows the status of the node (UN=up, DN=down):

  ![nodetool status output]

- If the node is up, run `nodetool decommission (page 263)`.

  This assigns the ranges that the node was responsible for to other nodes and replicates the data appropriately.

  Use `nodetool netstats (page 300)` to monitor the progress.

- If the node is down, choose the appropriate option:
# If the cluster uses vnodes, remove the node using the `nodetool removenode` command.

# If the cluster does not use vnodes, before running the `nodetool removenode` command, adjust your tokens (page 164) to evenly distribute the data across the remaining nodes to avoid creating a hot spot.

* If `removenode` fails, run `nodetool assassinate` (page 252).

## Switching snitches

Because snitches (page 28) determine how Cassandra distributes replicas, the procedure to switch snitches depends on whether or not the topology of the cluster will change:

- If data has not been inserted into the cluster, there is no change in the network topology. This means that you only need to set the snitch; no other steps are necessary.
- If data has been inserted into the cluster, it’s possible that the topology has changed and you will need to perform additional steps.
- If data has been inserted into the cluster that must be kept, change the snitch without changing the topology. Then add a new datacenter with new nodes and racks as desired. Finally, remove nodes from the old datacenters and racks. Simply altering the snitch and replication to move some nodes to a new datacenter will result in data being replicated incorrectly.

A change in topology means that there is a change in the datacenters and/or racks where the nodes are placed. Topology changes may occur when the replicas are placed in different places by the new snitch. Specifically, the replication strategy places the replicas based on the information provided by the new snitch. The following examples demonstrate the differences:

- **No topology change**
  
  **Change from:** five nodes using the RackInferringSnitch (page 29) in a single datacenter
  
  **To:** five nodes in one datacenter and 1 rack using a network snitch such as the GossipingPropertyFileSnitch (page 31)

- **Topology changes**
  
  # **Change from:** 5 nodes using the RackInferringSnitch (page 29) in a single datacenter
  
  **To:** 5 nodes in 2 datacenters using the PropertyFileSnitch (page 30) (add a datacenter).

  **Note:** If "splitting" one datacenter into two, create a new datacenter (page 180) with new nodes. Alter the keyspace (page ___) replication settings for the keyspace (page ___) that originally existed to reflect that two datacenters now exist. Once data is replicated to the new datacenter,
remove the number of nodes from the original datacenter that have "moved" to the new datacenter.

# Change From: 5 nodes using the PropertyFileSnitch (page 30) in a single datacenter

To: 5 nodes in 1 datacenter and 2 racks using the RackInferringSnitch (page 29) (add rack information).

Steps for switching snitches:

1. Create a properties file with datacenter and rack information.
   - cassandra-rackdc.properties
     GossipingPropertyFileSnitch (page 31), Ec2Snitch (page 32), and Ec2MultiRegionSnitch (page 33) only.
   - cassandra-topology.properties
     All other network snitches.

2. Copy the cassandra-rackdc.properties or cassandra-topology.properties file to the Cassandra configuration directory on all the cluster's nodes. They won't be used until the new snitch is enabled.

   The location of the cassandra-topology.properties file depends on the type of installation:

   | DataStax Enterprise 5.0 Installer- | /etc/dse/cassandra/cassandra-topology.properties |
   | Services and package installations |                                              |
   | DataStax Enterprise 5.0 Installer-No Services and tarball installations | install_location/resources/ cassandra/conf/cassandra-topology.properties |
   | Cassandra package installations | /etc/cassandra/cassandra-topology.properties |
   | Cassandra tarball installations | install_location/conf/cassandra-topology.properties |

   The location of the cassandra-rackdc.properties file depends on the type of installation:

   | DataStax Enterprise 5.0 Installer- | /etc/dse/cassandra/cassandra-rackdc.properties |
   | Services and package installations |                                              |
   | DataStax Enterprise 5.0 Installer-No Services and tarball installations | install_location/resources/ cassandra/conf/cassandra-rackdc.properties |
### Operations

<table>
<thead>
<tr>
<th>Cassandra package installations</th>
<th>/etc/cassandra/cassandra-rackdc.properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-rackdc.properties</td>
</tr>
</tbody>
</table>

The location of the **cassandra.yaml** file depends on the type of installation:

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>
<th>/etc/dse/cassandra/cassandra.yaml</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

3. Change the snitch for each node in the cluster in the node’s cassandra.yaml file. For example:

```
endpoint_snitch: GossipingPropertyFileSnitch
```

4. If the topology has not changed, you can restart each node one at a time. Any change in the cassandra.yaml file requires a node restart.

5. If the topology of the network has changed, but no datacenters are added:
   
   a. Shut down all the nodes, then restart them.
   
   b. Run a sequential repair (page 311) and nodetool cleanup (page 255) on each node.

6. If the topology of the network has changed and a datacenter is added:
   
   a. Create a new datacenter. (page 180)
   
   b. Replicate data into new datacenter. Remove nodes (page 191) from old datacenter.
   
   c. Run a sequential repair (page 311) and nodetool cleanup (page 255) on each node.

   **Caution:** DataStax recommends stopping repair operations during topology changes; the Repair Service does this automatically. Repairs
running during a topology change are likely to error when they involve moving ranges.

7. If migrating from the PropertyFileSnitch to the GossipingPropertyFileSnitch, remove the cassandra-topology.properties file from each node on any new cluster after the migration is complete.

Related information:
Snitches [A snitch determines which datacenters and racks nodes belong to.] (page 28)

Changing keyspace replication strategy

A keyspace is created with a strategy. For development work, the SimpleStrategy class is acceptable. For production work, the NetworkTopologyStrategy class must be set. To change the strategy, two steps are required. Altering the distribution of nodes within multiple datacenters when data is present should be accomplished by adding a datacenter, and then adding data to the new nodes in the new datacenter and removing nodes from the old datacenter.

• Change the snitch (page 192) to a network-aware setting.
• Alter the keyspace properties using the ALTER KEYSPACE command. For example, the keyspace cycling set to SimpleStrategy is switched to NetworkTopologyStrategy for a single datacenter DC1.

```cql
CQLSH> ALTER KEYSPACE cycling WITH REPLICAATION = {'class': 'NetworkTopologyStrategy', 'DC1': 3};
```

Note: Datacenter names are case sensitive. Verify the case of the using utility, such as dsetool status.

• Alter the keyspace properties using the ALTER KEYSPACE command. For example, the keyspace cycling set to SimpleStrategy is switched to NetworkTopologyStrategy. Altering a keyspace to add a datacenter involves additional steps. Simply altering the keyspace may lead to faulty data replication. See switching snitches (page 192) for additional information.

```cql
CQLSH> ALTER KEYSPACE cycling WITH REPLICAATION = {'class': 'NetworkTopologyStrategy', 'DC1': 3, 'DC2': 2};
```

• Run nodetool-repair (page 311) using the -full option on each node affected by the change. For details, see Updating the replication factor (page ).

It is possible to restrict the replication of a keyspace to selected datacenters, or a single datacenter. To do this, use the NetworkTopologyStrategy and set the replication factors of the excluded datacenters to 0 (zero), as in the following example:
Edge cases for transitioning or migrating a cluster

The information in this topic is intended for the following types of scenarios (without any interruption of service):

- Transition a cluster on EC2 to a cluster on Amazon virtual private cloud (VPC).
- Migrate from a cluster when the network separates the current cluster from the future location.
- Migrate from an early Cassandra cluster to a recent major version.

The following method ensures that if something goes wrong with the new cluster, you still have the existing cluster until you no longer need it.

1. Set up and configure the new cluster as described in Initializing a cluster (page 168).
   
   **Note:** If you’re not using vnodes, be sure to configure the token ranges in the new nodes to match the ranges in the old cluster.

2. Set up the schema for the new cluster using CQL (page ).

3. Configure your client to write to both clusters.

   Depending on how the writes are done, code changes may be needed. Be sure to use identical consistency levels.

4. Ensure that the data is flowing to the new nodes so you won’t have any gaps when you copy the snapshots to the new cluster in step 6.

5. **Snapshot** (page 203) the old EC2 cluster.

6. Copy the data files from your keyspaces to the nodes.

   - You may be able to copy the data files to their matching nodes in the new cluster, which is simpler and more efficient. This will work if:
     
     ```
     # You are not using vnodes
     # The destination is not a different version of Cassandra
     # The node ratio is 1:1
     ```

   - If the clusters are different sizes or if you are using vnodes, use the `sstableloader` (Cassandra bulk loader) (page 388) (sstableloader).

7. You can either switch to the new cluster all at once or perform an incremental migration.
For example, to perform an incremental migration, you can set your client to designate a percentage of the reads that go to the new cluster. This allows you to test the new cluster before decommissioning the old cluster.

8. Decommission the old cluster, as described in Decommissioning a datacenter (page 191).

**Adding single-token nodes to a cluster**

Steps for adding nodes in single-token architecture clusters, not vnodes.

To add capacity to a cluster, introduce new nodes in stages or by adding an entire datacenter (page 199). Use one of the following methods:

- **Add capacity by doubling the cluster size**: Adding capacity by doubling (or tripling or quadrupling) the number of nodes is less complicated when assigning tokens. Using this method, existing nodes keep their existing token assignments, and the new nodes are assigned tokens that bisect (or trisect) the existing token ranges.

- **Add capacity for a non-uniform number of nodes**: When increasing capacity with this method, you must recalculate tokens for the entire cluster, and assign the new tokens to the existing nodes.

**Note**: For DataStax Enterprise clusters, you can use OpsCenter to rebalance a cluster (page 183).

1. Calculate the tokens for the nodes based on your expansion strategy using the Token Generating Tool (page 164).

2. Install Cassandra (page 80) and configure Cassandra on each new node.

3. If Cassandra starts automatically (Debian), stop (page 176) the node and clear (page 177) the data.

4. Configure cassandra.yaml on each new node:
   - **auto_bootstrap (page 99)**: If false, set it to true.
     
     This option is not listed in the default cassandra.yaml configuration file and defaults to true.
   - **cluster_name (page 87)**
   - **listen_address (page 87)/broadcast_address (page 100)**: Usually leave blank. Otherwise, use the IP address or host name that other Cassandra nodes use to connect to the new node.
   - **endpoint_snitch (page 28)**
   - **initial_token (page 100)**: Set according to your token calculations.
Caution: If this property has no value, Cassandra assigns the node a random token range and results in a badly unbalanced ring.

- **seed_provider (page 92):** Make sure that the new node lists at least one seed node in the existing cluster.

  Seed nodes cannot bootstrap (page ). Make sure the new nodes are not listed in the -seeds list. Do not make all nodes seed nodes. See Internode communications (gossip) (page 21).

  - Change any other non-default settings in the new nodes to match the existing nodes. Use the diff command to find and merge any differences between the nodes.

5. Depending on the snitch, assign the datacenter and rack names in the cassandra-topology.properties or cassandra-rackdc.properties for each node.

6. Start Cassandra (page 176) on each new node in two minutes intervals with consistent.rangemovement turned off:

   - **Package installations:** To each bootstrapped node, add the following option to the /usr/share/cassandra/cassandra-env.sh file and then start Cassandra:

     ```
     JVM_OPTS="$JVM_OPTS -Dcassandra.consistent.rangemovement=false
     ```

   - **Tarball installations:**

     ```
     $ bin/dse cassandra -Dcassandra.consistent.rangemovement=false
     #Starts DataStax Enterprise
     ```

The following operations are resource intensive and should be done during low-usage times.

7. After the new nodes are fully bootstrapped, use nodetool move (page 299) to assign the new initial_token value to each node that requires one, one node at a time.

8. After all nodes have their new tokens assigned, run nodetool cleanup (page 255) on each node in the cluster and wait for cleanup to complete on each node before doing the next node.

   This step removes the keys that no longer belong to the previously existing nodes.

   The location of the cassandra-rackdc.properties file depends on the type of installation:

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>
<th>/etc/dse/cassandra/cassandra-rackdc.properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-rackdc.properties</td>
</tr>
</tbody>
</table>
Cassandra package installations  
/etc/cassandra/cassandra-rackdc.properties  

Cassandra tarball installations  
install_location/conf/cassandra-rackdc.properties

The location of the `cassandra-topology.properties` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-topology.properties</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-topology.properties</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-topology.properties</td>
</tr>

**Adding a datacenter to a single-token architecture cluster**

Steps for adding a datacenter to single-token architecture clusters, not vnodes.

1. Ensure that you are using `NetworkTopologyStrategy (page 61)` for all keyspaces.

2. For each new node, edit the configuration properties in the `cassandra.yaml` file:
   - Set `auto_bootstrap` to `False`.
   - Set the `initial_token`. Be sure to offset the tokens in the new datacenter, see `Generating tokens (page 164)`.
   - Set the `cluster name`.
   - Set any other non-default settings.
   - Set the `seed lists (page 92)`. Every node in the cluster must have the same list of seeds and include at least one node from each datacenter. Typically one to three seeds are used per datacenter.
3. Update either the properties file on all nodes to include the new nodes. You do not need to restart.
   • GossipingPropertyFileSnitch: cassandra-rackdc.properties
   • PropertyFileSnitch: cassandra-topology.properties

4. Ensure that your client does not auto-detect the new nodes so that they aren’t contacted by the client until explicitly directed.

5. If using a QUORUM consistency level (page 61) for reads or writes, check the LOCAL_QUORUM or EACH_QUORUM consistency level to make sure that the level meets the requirements for multiple datacenters.

6. Start the new nodes (page 176).

7. The GossipingPropertyFileSnitch always loads cassandra-topology.properties when that file is present. Remove the file from each node on any new cluster or any cluster migrated from the PropertyFileSnitch.

8. After all nodes are running in the cluster:
   a. Change the replication factor (page ) for your keyspace for the expanded cluster.
   b. Run nodetool rebuild (page 304) on each node in the new datacenter.

The location of the cassandra-rackdc.properties file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-rackdc.properties</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-rackdc.properties</td>
</tr>
</tbody>
</table>

The location of the cassandra-topology.properties file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-topology.properties</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-topology.properties</td>
</tr>
</tbody>
</table>
Replacing a dead node in a single-architecture cluster

Steps for replacing nodes in single-token architecture clusters, not vnodes.

1. Confirm that the node is dead using `nodetool ring (page 318)` on any live node in the cluster.
   
   A *Down* status indicates the dead node:

   ![nodetool ring output]

2. Install Cassandra *(page 80)* on the replacement node.

3. Remove any pre-existing Cassandra data on the replacement node:

   ```sh
   $ sudo rm -rf /var/lib/cassandra/*
   ```

4. Set `auto_bootstrap: true`.
   
   If `auto_bootstrap` is not in the `cassandra.yaml` file, it automatically defaults to `true`.

5. Set the `initial_token` in the `cassandra.yaml` file to the value of the dead node's token -1.

   ```yaml
   initial_token: 28356863910078205288614550619314017620
   ```
6. Configure any non-default settings in the node’s cassandra.yaml to match your existing cluster.

7. **Start the new node (page 176).**

8. After the new node has finished bootstrapping, check that it is up using nodetool ring.

9. Run nodetool repair (page 311) on each keyspace to ensure the node is fully consistent:

   ```
   $ nodetool repair -h 10.46.123.12 keyspace_name
   ```

10. **Remove the dead node.**

| The location of the cassandra.yaml (page ) file depends on the type of installation: |
|---------------------------------|-----------------------------------------------|
| DataStax Enterprise 5.0 Installer-Services and package installations | /etc/dse/cassandra/cassandra.yaml |
| DataStax Enterprise 5.0 Installer-No Services and tarball installations | install_location/resources/cassandra/conf/cassandra.yaml |
| Cassandra package installations | /etc/cassandra/cassandra.yaml |
| Cassandra tarball installations | install_location/resources/cassandra/conf/cassandra.yaml |

**Backing up and restoring data**

**Warning:** Always run nodetool cleanup (page 255) before taking a snapshot for restore. Otherwise invalid replicas, that is replicas that have been superseded by new, valid replicas on newly added nodes can get copied to the target when they should not. This results in old data showing up on the target.

**About snapshots**

Cassandra backs up data by taking a snapshot of all on-disk data files (SSTable files) stored in the data directory. You can take a snapshot of all keyspaces, a single keyspace, or a single table while the system is online.

Using a parallel ssh tool (such as pssh), you can snapshot an entire cluster. This provides an eventually consistent backup. Although no one node is guaranteed to be consistent with its replica nodes at the time a snapshot is taken, a restored snapshot resumes consistency using Cassandra's built-in consistency mechanisms.

After a system-wide snapshot is performed, you can enable incremental backups on each node to backup data that has changed since the last snapshot: each time a memtable is flushed to disk and an SSTable is created, a hard link is copied into a /backups subdirectory of the data directory (provided JNA is enabled). Compacted SSTables will not
create hard links in /backups because these SSTables do not contain any data that has not already been linked.

**Taking a snapshot**

Snapshots are taken per node using the nodetool snapshot (page 338) command. To take a global snapshot, run the nodetool snapshot command using a parallel ssh utility, such as `pssh`.

A snapshot first flushes all in-memory writes to disk, then makes a hard link of the SSTable files for each keyspace. You must have enough free disk space on the node to accommodate making snapshots of your data files. A single snapshot requires little disk space. However, snapshots can cause your disk usage to grow more quickly over time because a snapshot prevents old obsolete data files from being deleted. After the snapshot is complete, you can move the backup files to another location if needed, or you can leave them in place.

**Note:** Cassandra can only restore data from a snapshot when the table schema exists. It is recommended that you also backup the schema. See `DESCRIBE SCHEMA` in `DESCRIBE` (page ).

1. Run nodetool cleanup (page 255) to ensure that invalid replicas are removed.
   
   ```
   $ nodetool cleanup cycling
   ```

2. Run the nodetool snapshot command, specifying the hostname, JMX port, and keyspace. For example:
   
   ```
   $ nodetool -h localhost -p 7199 snapshot mykeyspace
   ```

   The snapshot is created in `data_directory/keyspace_name/table_name-UUID/snapshots/snapshot_name` directory. Each snapshot directory contains numerous `.db` files that contain the data at the time of the snapshot.

   For example:
   
   - **Cassandra package installations**: `/var/lib/cassandra/data/mykeyspace/users-081a1500136111e482d09318a3b15cc2/snapshots/1406227071618/mykeyspace-users-ka-1-Data.db`
   - **Cassandra tarball installations**: `install_location/data/data/mykeyspace/users-081a1500136111e482d09318a3b15cc2/snapshots/1406227071618/mykeyspace-users-ka-1-Data.db`

   The location of the `data` directory depends on the type of installation:

   | DataStax Enterprise 5.0 Installer-Services and package installations | `/var/lib/cassandra/data` |

---

Apache Cassandra 3.0 for DSE 5.0 (Earlier version)
### Deleting snapshot files

When taking a snapshot, previous snapshot files are not automatically deleted. You should remove old snapshots that are no longer needed.

The `nodetool cleansnapshot (page 256)` command removes all existing snapshot files from the snapshot directory of each keyspace. You should make it part of your back-up process to clear old snapshots before taking a new one.

1. To delete all snapshots for a node, run the `nodetool cleansnapshot` command. For example:
   ```bash
   $ nodetool -h localhost -p 7199 cleansnapshot
   ```
   To delete snapshots on all nodes at once, run the `nodetool cleansnapshot` command using a parallel ssh utility.

2. To delete a single snapshot, run the `cleansnapshot` command with the snapshot name:
   ```bash
   $ nodetool cleansnapshot -t <snapshot_name>
   ```
   The file name and path vary according to the type of snapshot. See `nodetools snapshot (page 338)` for details about snapshot names and paths.

### Enabling incremental backups

When incremental backups are enabled (disabled by default), Cassandra hard-links each memtable-flushed SSTable to a backups directory under the keyspace data directory. This allows storing backups offsite without transferring entire snapshots. Also, incremental backups combined with snapshots to provide a dependable, up-to-date backup mechanism. Compacted SSTables will not create hard links in `/backups` because these SSTables do not contain any data that has not already been linked. A snapshot at a point in time, plus all incremental backups and commit logs since that time form a complete backup.

As with snapshots, Cassandra does not automatically clear incremental backup files. DataStax recommends setting up a process to clear incremental backup hard-links each time a new snapshot is created.

The location of the `cassandra.yaml` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>/var/lib/cassandra/data</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/var/lib/cassandra/data</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/data/data</td>
</tr>
</tbody>
</table>
1. Edit the cassandra.yaml configuration file on each node in the cluster and change the value of `incremental_backups (page 95)` to true.

## Restoring from a snapshot

Restoring a keyspace from a snapshot requires all snapshot files for the table, and if using incremental backups, any incremental backup files created after the snapshot was taken. Streamed SSTables (from repair, decommission, and so on) are also hardlinked and included.

**Note:** Restoring from snapshots and incremental backups temporarily causes intensive CPU and I/O activity on the node being restored.

On this page:
- Restoring from local nodes *(page 205)*
- Restoring from centralized backups *(page 206)*

### Restoring from local nodes

This method copies the SSTables from the snapshots directory into the correct data directories.

1. Make sure the table schema exists.

   Cassandra can only restore data from a snapshot when the table schema exists. If the schema does not exist and has not been backed up, you must recreate the schema.

2. If necessary, truncate *(page 257)* the table.

   **Note:** You may not need to truncate under certain conditions. For example, if a node lost a disk, you might restart before restoring so that the node continues to receive new writes before starting the restore procedure.

   Truncating is usually necessary. For example, if there was an accidental deletion of data, the tombstone from that delete has a later write timestamp than the data in the snapshot. If you restore without truncating (removing the tombstone), Cassandra continues to shadow the restored data. This behavior also occurs for other types of overwrites and causes the same problem.

3. Locate the most recent snapshot folder. For example:
data_directory/keyspace_name/table_name-UUID/
snapshots/snapshot_name

4. Copy the most recent snapshot SSTable directory to the
data_directory/keyspace/table_name-UUID directory.

The location of the data directory depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Directory Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td>/var/lib/cassandra/data</td>
</tr>
<tr>
<td>installations</td>
<td></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>/var/lib/cassandra/data</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/var/lib/cassandra/data</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/data/data</td>
</tr>
</tbody>
</table>

5. Run nodetool refresh (page 307).

   Note: If the node is on DataStax Enterprise versions earlier than 5.0.10, restart your nodes (page 176). This restart is required because nodetool refresh (page 307) does not respect the existing LCS levels on disk, which results in a compaction backlog.

Restoring from centralized backups

This method uses sstableloader (page 388) to restore snapshots.

1. Make sure the table schema exists.

   Cassandra can only restore data from a snapshot when the table schema exists. If the schema does not exist and has not been backed up, you must recreate the schema.

2. If necessary, truncate (page ) the table.

   Note: You may not need to truncate under certain conditions. For example, if a node lost a disk, you might restart before restoring so that the node continues to receive new writes before starting the restore procedure.

   Truncating is usually necessary. For example, if there was an accidental deletion of data, the tombstone from that delete has a later write timestamp than the data in the snapshot. If you restore without truncating (removing the tombstone), Cassandra continues to shadow the restored data. This behavior also occurs for other types of overwrites and causes the same problem.
3. Restore the most recent snapshot using the **sstableloader** *(page 388)* tool on the backed-up SSTables.

   The sstableloader streams the SSTables to the correct nodes. You do not need to remove the commitlogs or drain or restart the nodes.

### Restoring a snapshot into a new cluster

Suppose you want to copy a snapshot of SSTable data files from a three node Cassandra cluster with vnodes enabled (256 tokens) and recover it on another newly created three node cluster (256 tokens). The token ranges will not match, because the token ranges cannot be exactly the same in the new cluster. You need to specify the tokens for the new cluster that were used in the old cluster.

**Note:** This procedure assumes you are familiar with *restoring a snapshot* *(page 205)* and configuring and *initializing a cluster* *(page 168)*.

The location of the **cassandra.yaml** *(page )* file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>File Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/ conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/ conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

To recover the snapshot on the new cluster:

1. From the old cluster, retrieve the list of tokens associated with each node’s IP:

   ```
   $ nodetool ring | grep -w ip_address_of_node | awk '{print $NF ","}' | xargs
   ```

2. In the cassandra.yaml file for each node in the new cluster, add the list of tokens you obtained in the previous step to the **initial_token** *(page 100)* parameter using the same **num_tokens** setting as in the old cluster.

3. Make any other necessary changes in the new cluster’s cassandra.yaml and property files so that the new nodes match the old cluster settings. Make sure the seed nodes are set for the new cluster.

4. Clear the system table data from each new node:

   ```
   $ sudo rm -rf /var/lib/cassandra/data/system/*
   ```
This allows the new nodes to use the initial tokens defined in the cassandra.yaml when they restart.

5. Start each node using the specified list of token ranges in new cluster's cassandra.yaml:

```
initial_token: -9211270970129494930, -9138351317258731895, -8980763462514965928, ...
```

6. Create schema in the new cluster. All the schemas from the old cluster must be reproduced in the new cluster.

7. **Stop the node (page 176).** Using `nodetool refresh` is unsafe because files within the data directory of a running node can be silently overwritten by identically named just-flushed SSTables from memtable flushes or compaction. Copying files into the data directory and restarting the node will not work for the same reason.

8. **Restore the SSTable files snapshotted (page 205) from the old cluster onto the new cluster using the same directories, while noting that the UUID component of target directory names has changed.** Without restoration, the new cluster will not have data to read upon restart.

9. Restart the node.

**Recovering from a single disk failure using JBOD**

Steps for recovering from a single disk failure in a disk array using JBOD (just a bunch of disks).

Cassandra might not fail from the loss of one disk in a JBOD array, but some reads and writes may fail when:

- The operation's consistency level is ALL.
- The data being requested or written is stored on the defective disk.
- The data to be compacted is on the defective disk.

It's possible that you can simply replace the disk, restart Cassandra, and run `nodetool repair`. However, if the disk crash corrupted the Cassandra system table, you must remove the incomplete data from the other disks in the array. The procedure for doing this depends on whether the cluster uses `vnodes (page)` or single-token architecture.

These steps are supported for Cassandra versions 3.2 and later. If a disk fails on a node in a cluster using an earlier version of Cassandra, replace the node (page 185).

1. Verify that the node has a defective disk and identify the disk, by checking the logs (page 160) on the affected node.
Disk failures are logged in **FILE NOT FOUND** entries, which identifies the mount point or disk that has failed.

2. If the node is still running, stop Cassandra *(page 176)* and shut down the node.

3. Replace the defective disk and restart the node.

4. If the node cannot restart:
   a. Try restarting Cassandra without bootstrapping the node:
      
      Cassandra package installations:
      a. Add the following option to `cassandra-env.sh` file:
         
         ```
         JVM_OPTS=""$JVM_OPTS -Dcassandra.allow_unsafe_replace=true"
         ```
      b. **Start the node *(page 176)*.**
      c. After the node bootstraps, remove the `-Dcassandra.allow_unsafe_replace=true` parameter from `cassandra-env.sh`.
      d. **Restart the node *(page 176)*.**

      Cassandra tarball installations:
      • **Start Cassandra with this option:**
         
         ```
         $ sudo bin/dse cassandra
         Dcassandra.allow_unsafe_replace=true #Starts DataStax Enterprise
         ```

5. If Cassandra restarts, run `nodetool repair *(page 311)*` on the node. If not, **replace the node *(page 185)*.**

6. If the repair succeeds, the node is restored to production. Otherwise, go to 7 *(page 209)* or 8 *(page 210)*.

7. For a cluster using vnodes:
   a. On the affected node, clear the `system` directory on each functioning drive.
      
      Example for a node with a three disk JBOD array:
      
      ```
      $ -/mnt1/cassandra/data
      $ -/mnt2/cassandra/data
      ```
Operations

If `mnt1` has failed:

```bash
$ rm -fr /mnt2/cassandra/data/system
$ rm -fr /mnt3/cassandra/data/system
```

**b.** Restart Cassandra without bootstrapping as described in 4 (page 209):

```bash
$ sudo bin/dse cassandra -Dcassandra.allow_unsafe_replace=true #Restarts DataStax Enterprise
```

**c.** Run `nodetool repair` (page 311) on the node.

If the repair succeeds, the node is restored to production. If not, replace the dead node (page 185).

**8.** For a cluster single-token nodes:

**a.** On one of the cluster's working nodes, run `nodetool ring` (page 318) to retrieve the list of the repaired node's tokens:

```bash
$ nodetool ring | grep ip_address_of_node | awk '{print $NF ","}' | xargs
```

**b.** Copy the output of the `nodetool ring` into a spreadsheet (space-delimited).

**c.** Edit the output, keeping the list of tokens and deleting the other columns.

**d.** On the node with the new disk, open the `cassandra.yaml` file and add the tokens (as a comma-separated list) to the `initial_token` (page 100) property.

**e.** Change any other non-default settings in the new nodes to match the existing nodes. Use the `diff` command to find and merge any differences between the nodes.

If the repair succeeds, the node is restored to production. If not, replace the node (page 185).

**f.** On the affected node, clear the `system` directory on each functioning drive.

Example for a node with a three disk JBOD array:

```bash
$ -/mnt1/cassandra/data
$ -/mnt2/cassandra/data
```
Operations

$ -/mnt3/cassandra/data

If mnt1 has failed:

$ rm -fr /mnt2/cassandra/data/system
$ rm -fr /mnt3/cassandra/data/system

g. Restart Cassandra without bootstrapping as described in 4 (page 209):

$ sudo bin/dse cassandra -
Dcassandra.allow_unsafe_replace=true #Restarts DataStax Enterprise

h. Run nodetool repair (page 311) on the node.

If the repair succeeds, the node is restored to production. If not, replace the node (page 185).

The location of the cassandra.yaml (page ) file depends on the type of installation:

| DataStax Enterprise 5.0 Installer-Services and package installations | /etc/dse/cassandra/cassandra.yaml |
| DataStax Enterprise 5.0 Installer-No Services and tarball installations | install_location/resources/cassandra/conf/cassandra.yaml |
| Cassandra package installations | /etc/cassandra/cassandra.yaml |
| Cassandra tarball installations | install_location/resources/cassandra/conf/cassandra.yaml |

The location of the cassandra-rackdc.properties file depends on the type of installation:

| DataStax Enterprise 5.0 Installer-Services and package installations | /etc/dse/cassandra/cassandra-rackdc.properties |
| DataStax Enterprise 5.0 Installer-No Services and tarball installations | install_location/resources/cassandra/conf/cassandra-rackdc.properties |
| Cassandra package installations | /etc/cassandra/cassandra-rackdc.properties |
| Cassandra tarball installations | install_location/conf/cassandra-rackdc.properties |

The location of the cassandra-topology.properties file depends on the type of installation:

| DataStax Enterprise 5.0 Installer-Services and package installations | /etc/dse/cassandra/cassandra-topology.properties |
DataStax Enterprise 5.0 Installer-No Services and tarball installations

install_location/resources/cassandra/conf/cassandra-topology.properties

Cassandra package installations

/etc/cassandra/cassandra-topology.properties

Cassandra tarball installations

install_location/conf/cassandra-topology.properties

The location of the cassandra-env.sh file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>cassandra-env.sh Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

Repairing nodes

Over time, data in a replica can become inconsistent with other replicas due to the distributed nature of the database. Node repair corrects the inconsistencies so that eventually all nodes have the same and most up-to-date data. It is important part of regular maintenance for every Cassandra cluster.

Cassandra provides the following repair processes:

- **Hinted Handoff (page 213)**
  
  If a node becomes unable to receive a particular write, the write's coordinator node preserves the data to be written as a set of hints. When the node comes back online, the coordinator effects repair by handing off hints so that the node can catch up with the required writes.

- **Read Repair (page 215)**
  
  During the read path, a query assembles data from several nodes. The coordinator node for this write compares the data from each replica node. If any replica node has outdated data, the coordinator node sends it the most recent version. The scope of this type of repair depends on the keyspace's replication factor. During a write, Cassandra collects only enough replica data to satisfy the replication factor, and only performs read repair on nodes that participate in that write operation.

  But Cassandra can also choose a write at random and perform read repair on all replicas, regardless of the replication factor.

- **Anti-Entropy Repair (page 215)**
Cassandra provides the `nodetool repair` tool to ensure data consistency across replicas; it compares the data across all replicas and then updates the data to the most recent version. Use `nodetool repair` as part of your regular maintenance routine.

**Warning:** DataStax recommends stopping repair operations during topology changes; the Repair Service does this automatically. Repairs running during a topology change are likely to error when it involves moving ranges.

You can use Cassandra settings or Cassandra tools to configure each type of repair. For details on when to use each type of repair and how to configure each one, see the pages listed above.

**Hinted Handoff: repair during write path**

On occasion, a node becomes unresponsive while data is being written. Reasons for unresponsiveness are hardware problems, network issues, or overloaded nodes that experience long garbage collection (GC) pauses. By design, hinted handoff inherently allows Cassandra to continue performing the same number of writes even when the cluster is operating at reduced capacity.

After the failure detector marks a node as down, missed writes are stored by the coordinator for a period of time, if hinted handoff is enabled in the `cassandra.yaml` file. In Cassandra 3.0 and later, the hint is stored in a local `hints` directory on each node for improved replay. The hint consists of a target ID for the downed node, a hint ID that is a time UUID for the data, a message ID that identifies the Cassandra version, and the data itself as a blob. Hints are flushed to disk every 10 seconds, reducing the staleness of the hints. When gossip discovers when a node has comes back online, the coordinator replays each remaining hint to write the data to the newly-returned node, then deletes the hint file. If a node is down for longer than `max_hint_window_in_ms` (3 hours by default), the coordinator stops writing new hints.

The coordinator also checks every ten minutes for hints corresponding to writes that timed out during an outage too brief for the failure detector to notice through gossip. If a replica node is overloaded or unavailable, and the failure detector has not yet marked the node as down, then expect most or all writes to that node to fail after the timeout triggered by `write_request_timeout_in_ms` (10 seconds by default). The coordinator returns a `TimeOutException` exception, and the write will fail but a hint will be stored. If several nodes experience brief outages simultaneously, substantial memory pressure can build up on the coordinator. The coordinator tracks how many hints it is currently writing, and if the number increases too much, the coordinator refuses writes and throws the `OverloadedException` exception.

The consistency level of a write request affects whether hints are written and a write request subsequently fails. If the cluster consists of two nodes, A and B, with a replication factor of 1, each row is stored on only one node. Suppose node A is the coordinator, but goes down before a row K is written to it with a consistency level of ONE. In this case, the consistency level specified cannot be met, and since node A is the coordinator, it cannot store a hint. Node B cannot write the data, because it has not received the data as the coordinator nor
has a hint been stored. The coordinator checks the number of replicas that are up and will not attempt to write the hint if the consistency level specified by a client cannot be met. A hinted handoff failure occurs and will return a `UnavailableException` exception. The write request fails and the hint is not written.

In general, the recommendation is to have enough nodes in the cluster and a replication factor sufficient to avoid write request failures. For example, consider a cluster consisting of three nodes, A, B, and C, with a replication factor of 2. When a row K is written to the coordinator (node A in this case), even if node C is down, the consistency level of ONE or QUORUM can be met. Why? Both nodes A and B will receive the data, so the consistency level requirement is met. A hint is stored for node C and written when node C comes up. In the meantime, the coordinator can acknowledge that the write succeeded.

For applications that want Cassandra to accept writes when all the normal replicas are down and consistency level ONE cannot be satisfied, Cassandra provides consistency level ANY. ANY guarantees that the write is durable and readable after an appropriate replica target becomes available and receives the hint replay.

Nodes that die might have stored undelivered hints, because any node can be a coordinator. The data on the dead node will be stale after a long outage as well. If a node has been down for an extended period of time, a manual repair (page 215) should be run.

At first glance, it seems that hinted handoff eliminates the need for manual repair, but this is not true because hardware failure is inevitable and has the following ramifications:

- Loss of the historical data necessary to tell the rest of the cluster exactly what data is missing.
- Loss of hints-not-yet-replayed from requests that the failed node coordinated.
When removing a node from the cluster by decommissioning the node or by using the `nodetool removenode` command, Cassandra automatically removes hints targeting the node that no longer exists. Cassandra also removes hints for dropped tables.

For more explanation about hint storage, see What's Coming to Cassandra in 3.0: Improved Hint Storage and Delivery or an older blog that discusses the basics, Modern hinted handoff.

The location of the `cassandra.yaml` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>

</tbody>
</table>

**Read Repair: repair during read path**

Read repair improves consistency in a Cassandra cluster with every read request.

In a read, the coordinator node sends a data request to one replica node and digest requests to others for consistency level (CL) greater than `ONE`. If all nodes return consistent data, the coordinator returns it to the client. For a description of how Cassandra handles inconsistency among replicas, see How are read requests accomplished? (page 65).

In read repair, Cassandra sends a digest request to each replica not directly involved in the read. Cassandra compares all replicas and writes the most recent version to any replica node that does not have it. If the query’s consistency level (page 63) is above `ONE`, Cassandra performs this process on all replica nodes in the foreground before the data is returned to the client. Read repair repairs any node queried by the read. This means that for a consistency level of `ONE`, no data is repaired because no comparison takes place. For `QUORUM`, only the nodes that the query touches are repaired, not all nodes.

Read repair cannot be performed on tables that use `DateTieredCompactionStrategy` (page 241), due to the method of checking timestamps used in DTCS compaction. If your table uses `DateTieredCompactionStrategy`, set `read_repair_chance` to zero. For other compaction strategies, `read_repair_chance` is typically set to a value of 0.2.

**Manual repair: Anti-entropy repair**

Anti-entropy (page 215) node repairs are important for every Cassandra cluster. Frequent data deletions and downed nodes are common causes of data inconsistency. Use anti-entropy repair for routine maintenance and when a cluster needs fixing by running the `nodetool repair` command.

How does anti-entropy repair work?

DataStax Enterprise accomplishes anti-entropy repair using Merkle trees, similar to Dynamo and Riak. Anti-entropy is a process of comparing the data of all replicas and updating each replica to the newest version. DataStax Enterprise has two phases to the process:
1. Build a Merkle tree for each replica

2. Compare the Merkle trees to discover differences

Merkle trees are binary hash trees whose leaves are hashes of the individual key values. The leaf of a DataStax Enterprise Merkle tree is the hash of a row value. Each Parent node higher in the tree is a hash of its respective children. Because higher nodes in the Merkle tree represent data further down the tree, Cassandra can check each branch independently without requiring the coordinator node to download the entire data set. For anti-entropy repair DataStax Enterprise uses a compact tree version with a depth of 15 \(2^{15} = 32\text{K leaf nodes}\). For example, a node containing a million partitions with one damaged partition, about 30 partitions are streamed, which is the number that fall into each of the leaves of the tree. DataStax Enterprise works with smaller Merkle trees because they require less storage memory and can be transferred more quickly to other nodes during the comparison process.

After the initiating node receives the Merkle trees from the participating peer nodes, the initiating node compares every tree to every other tree. If a difference is detected, the differing nodes exchange data for the conflicting range(s), and the new data is written to SSTables. The comparison begins with the top node of the Merkle tree. If no difference is detected, then the data requires no repair. If any difference is detected, the process proceeds to the left child node and compares and then the right child node. When a node is found to differ, inconsistent data exists for the range that pertains to that node. All data that corresponds to the leaves below that Merkle tree node will be replaced with new data. For any given replica set, DataStax Enterprise performs validation compaction on only one replica at a time.
Merkle tree building is quite resource intensive, stressing disk I/O and using memory. Some of the options discussed here help lessen the impact on the cluster performance.

Run \texttt{nodetool repair} command on either a specified node or on all nodes if a node is not specified. The node that initiates the repair becomes the coordinator node for the operation. To build the Merkle trees, the coordinator node determines peer nodes with matching ranges of data. A major, or validation, compaction is triggered on the peer nodes. The validation compaction reads and generates a hash for every row in the stored column families, adds the result to a Merkle tree, and returns the tree to the initiating node. Merkle trees use hashes of the data, because in general, hashes will be smaller than the data itself. The \texttt{Repair in Cassandra} blog discusses this process in more detail.

\begin{itemize}
  \item \textbf{Note:} To switch from incremental to full repair, see \texttt{Changing repair strategies} (page 221).
\end{itemize}

**Full repair vs incremental repair (-full vs -inc)**

Full repair builds a full Merkle tree and compares it the data against the data on other nodes.

\begin{itemize}
  \item \textbf{Notice:} DSE changed the default behavior for \texttt{nodetool repair} as follows:
    \begin{itemize}
      \item \textbf{DSE 5.0.10 and later} runs full repair by default. To perform an incremental repair on a node running DSE 5.0.10 specify:
        \begin{verbatim}
        $ nodetool repair -inc
        \end{verbatim}
      \item \textbf{DSE 5.0.0-5.0.9} runs incremental repair. To perform a full repair on a node running DSE 5.0.0-5.0.9 specify:
        \begin{verbatim}
        $ nodetool repair -full
        \end{verbatim}
    \end{itemize}
\end{itemize}

Incremental repair compares all SSTables on the node and makes necessary repairs. An incremental repair persists data that has already been repaired, and only builds Merkle trees for unrepaired SSTables. Incremental repair marks the rows in an SSTable as repaired or unrepaired.
Incremental repairs work like full repairs, with an initiating node requesting Merkle trees from peer nodes with the same unrepaired data, and then comparing the Merkle trees to discover mismatches. Once the data has been reconciled and new SSTables built, the initiating node issues an anti-compaction command. Anti-compaction is the process of segregating repaired and unrepaired ranges into separate SSTables, unless the SSTable fits entirely within the repaired range. In the latter case, the SSTable metadata `repairedAt` is updated to reflect its repaired status.

Anti-compaction is handled differently, depending on the compaction strategy assigned to the data.

- Size-tiered compaction (STCS) splits repaired and unrepaired data into separate pools for separate compactions. A major compaction generates two SSTables, one for each pool of data.
- Leveled compaction (LCS) performs size-tiered compaction on unrepaired data. After repair completes, Cassandra moves data from the set of unrepaired SSTables to L0.
- Date-tiered (DTCS) splits repaired and unrepaired data into separate pools for separate compactions. A major compaction generates two SSTables, one for each pool of data. DTCS compaction should not use incremental repair.

Parallel vs Sequential repair (-seq)

Sequential repair takes action on one node after another. Parallel repair repairs all nodes with the same replica data at the same time. Datacenter parallel (-dc-par) combines sequential and parallel by simultaneously running a sequential repair in all datacenters; one node in each datacenter runs repair until the repair is complete.

Sequential repair takes a snapshot of each replica. Snapshots are hardlinks to existing SSTables. They are immutable and require almost no disk space. The snapshots are active while the repair proceeds, then the database deletes them. When the coordinator node finds discrepancies in the Merkle trees, the coordinator node makes required repairs from the snapshots. For example, for a table in a keyspace with a Replication factor RF=3 and
replicas A, B, and C, the `repair` command takes a snapshot of each replica immediately and then repairs each replica from the snapshots sequentially (using snapshot A to repair replica B, then snapshot A to repair replica C, then snapshot B to repair replica C).

Parallel repair constructs the Merkle tables for all nodes in all datacenters at the same time. It works on nodes A, B, and C all at once. During parallel repair, the `dynamic snitch` processes queries for this table using a replica in the snapshot that is not undergoing repair. Use parallel repair to complete the repair quickly or when you have operational downtime that allows the resources to be completely consumed during the repair.

Datacenter parallel repair, unlike sequential repair, constructs the Merkle tables for all datacenters at the same time. Therefore, no snapshots are required (or generated).

Sequential repair is the default in DataStax Enterprise 4.8 and earlier. Parallel repair is the default for DataStax Enterprise 5.0 and later.

**Partitioner range ( -pr)**

Within a cluster, Cassandra stores a particular range of data on multiple nodes. If you run `nodetool repair` on one node at a time, Cassandra may repair the same range of data several times (depending on the replication factor used in the keyspace). If you use the partitioner range option ( -pr), `nodetool repair` only repairs a specified range of data once, rather than repeating the repair operation. This decreases the strain on network resources, although `nodetool repair` still builds Merkle trees for each replica.

**Note:** If you use this option, you must run `nodetool repair -pr` on every node in the cluster to repair all data. Otherwise, some ranges of data will not be repaired.

The partitioner range option is recommended for routine maintenance. Do not use it to repair a downed node. Do not use with incremental repair (default for Cassandra 3.0 and later).

**Local (-local, --in-local-dc) vs datacenter (dc, --in-dc) vs Cluster-wide repair**

Consider carefully before using `nodetool repair` across datacenters, instead of within a local datacenter. When you run repair locally on a node using `-local` or `--in-local-dc`, the command runs only on nodes within the same datacenter as the node that runs it. Otherwise, the command runs cluster-wide repair processes on all nodes that contain replicas, even those in different datacenters. For example, if you start `nodetool repair` over two datacenters, DC1 and DC2, each with a replication factor of 3, `repair` must build Merkle tables for 6 nodes. The number of Merkle Tree increases linearly for additional datacenters. Cluster-wide repair also increases network traffic between datacenters tremendously, and can cause cluster issues.

If the local option is too limited, consider using the `-dc` or `--in-dc` options, limiting repairs to a specific datacenter. This does not repair replicas on nodes in other datacenters, but it can decrease network traffic while repairing more nodes than the local options.

The `nodetool repair -pr` option is good for repairs across multiple datacenters.

**Additional notes for -local repairs:**
• The `nodetool repair` tool does not support the use of `-local` with the `-pr` option unless the datacenter's nodes have all the data for all ranges.
• Also, the tool does not support the use of `-local` with `-inc` (incremental repair).

**Note:** For Cassandra 2.2 and later, a recommended option for repairs across datacenters: use the `-dcpar` or `--dc-parallel` to repair datacenters in parallel.

**Endpoint range vs Subrange repair (`-st`, `--start-token`, `-et` `--end-token`)**

A repair operation runs on all partition ranges on a node, or endpoint range, unless you use the `-st` and `-et` (or `-start-token` and `-end-token`) options to run subrange repairs. When you specify a start token and end token, `nodetool repair` works between these tokens, repairing only those partition ranges.

Subrange repair is not a good strategy because it requires generated token ranges. However, if you know which partition has an error, you can target that partition range precisely for repair. This approach can relieve the problem known as overstreaming, which ties up resources by sending repairs to a range over and over.

Subrange repair involves more than just the `nodetool repair` command. A Java `describe_splits` call to ask for a split containing 32k partitions can be iterated throughout the entire range incrementally or in parallel to eliminate the overstreaming behavior. Once the tokens are generated for the split, they are passed to `nodetool repair -st <start_token> -et <end_token>`. The `-local` option can be used to repair only within a local data center to reduce cross data center transfer.

**When to run anti-entropy repair**

When to run anti-entropy repair is dependent on the characteristics of a Cassandra cluster. General guidelines are presented here, and should be tailored to each particular case.

**When is repair needed?**

Run repair in these situations:

• To routinely maintain node health.
  
  **Note:** Even if deletions never occur, schedule regular repairs. Setting a column to null is a delete.

• To recover a node after a failure while bringing it back into the cluster.

• To update data on a node containing data that is not read frequently, and therefore does not get read repair.

• To update data on a node that has been down.

• To recover missing data or corrupted SSTables. To do this, you must run non-incremental repair.

Guidelines for running routine node repair include:

• Run incremental repair daily, run full repairs weekly to monthly. Monthly is generally sufficient, but run more frequently if warranted.
**Important:** Full repair is useful for maintaining data integrity, even if deletions never occur.

- Use the parallel and partitioner range options, unless precluded by the scope of the repair.
- Run a full repair to eliminate anti-compaction. Anti-compaction is the process of splitting an SSTable into two SSTables, one with repaired data and one with non-repaired data. This has compaction strategy implications.

**Note:** Before you can run incremental repair, you must set the repaired state of each SSTable. For instructions, see Migrating to incremental repairs (page 222).

- Run repair frequently enough that every node is repaired before reaching the time specified in the `gc_grace_seconds (page 324)` setting. Deleted data is properly handled in the cluster if this requirement is met.
- Schedule routine node repair to minimize cluster disruption.
  - If possible, schedule repair operation for low-usage hours.
  - If possible, schedule repair operations on single nodes at a time.
- Increase the time value setting of `gc_grace_seconds` if data is seldom deleted or overwritten. For these tables, changing the setting will:
  - Minimizes impact to disk space.
  - Allow longer interval between repair operations.
- Mitigate heavy disk usage by configuring nodetool compaction throttling options (`setcompactionthroughput (page 326)` and `setcompactionthreshold (page 324)`) before running a repair.

Guidelines for running repair on a downed node:

- Do not use partitioner range, `-pr`.

**Changing repair strategies**

Change the method used for routine repairs from incremental or full repair. Repairing SSTables using anti-entropy repair (page 215) is required for database maintenance. A full repair of all SSTables on a node takes a lot of time and is resource-intensive. Incremental repair consumes less time and resources because it skips SSTables that are already marked as repaired.

**Migrating to full repairs**

Incremental repairs split the data into repaired and un repaired SSTables and mark the data state with metadata. Full repairs keeps the data together and uses no repair status flag. Before switching from incremental repairs to full repairs remove the status.
Operations

$ nodetool mark_unrepaired keyspace_name [table_name]

Migrating to incremental repairs

Repairing SSTables using anti-entropy repair (page 215) is a necessary part of Cassandra maintenance. A full repair of all SSTables on a node takes a lot of time and is resource-intensive. You can manage repairs with less service disruption using incremental repair (page 217). Incremental repair consumes less time and resources because it skips SSTables that are already marked as repaired.

Incremental repair works equally well with any compaction scheme — Size-Tiered Compaction (STCS) (page 42), Date-Tiered Compaction (DTCS) (page 46), Time-Window Compaction (TWCS) (page 44), or Leveled Compaction (LCS) (page 43).

In Cassandra 3.0 and later, switching from full repair to incremental repair is easier than before. However, the first system-wide incremental repair can take a long time, as Cassandra recompacts all SSTables according to the chosen compaction scheme. You can make this process less disruptive by migrating the cluster to incremental repair one node at a time.

Overview of the procedure

To migrate one Cassandra node to incremental repair:

1. Disable autocompaction on the node.
2. Run a full, sequential repair.
3. Stop the node.
4. Set the repairedAt metadata value to each SSTable that existed before you disabled compaction.
5. Restart Cassandra on the node.
6. Re-enable autocompaction on the node.

Prerequisites: Listing SSTables

Before you run a full repair on the node, list its SSTables. The existing SSTables may not be changed by the repair process, and the incremental repair process you run later will not process these SSTables unless you set the repairedAt value for each SSTable (see Step 4 (page 223) below).

You can find the node’s SSTables in one of the following locations:

- DataStax Enterprise 5.0 Installer-Services and package installations: /var/lib/cassandra/data
- DataStax Enterprise 5.0 Installer-No Services and tarball installations: /var/lib/cassandra/data
• Cassandra package installations:/var/lib/cassandra/data
• Cassandra tarball installations: install_location/data/data

This directory contains a subdirectory for each keyspace. Each of these subdirectories contains a set of files for each SSTable. The name of the file that contains the SSTable data has the following format:

\(<version\_code>-<generation>-<format>-Data.db\)

**Note:** You can mark multiple SSTables as a batch by running `sstablerepairedset` with a text file of filenames — see Step 4 *(*page 223)*.*

Migrating the node to incremental repair

**Note:** In RHEL and Debian installations, you must install the tools packages before you can follow these steps.

1. **Disable autocompaction on the node**

   From the `install_directory`:
   
   $ bin/nodetool disableautocompaction
   
   Running this command without parameters disables autocompaction for all keyspaces. For details, see `nodetool disableautocompaction (page 267)`.

2. **Run the default full, sequential repair**

   From the `install_directory`:
   
   $ bin/nodetool repair
   
   Running this command without parameters starts a full sequential repair of all SSTables on the node. This may take a substantial amount of time. For details, see `nodetool repair (page 311)`.

3. **Stop the node.**

4. **Set the `repairedAt` metadata value to each SSTable that existed before you disabled compaction.**

   Use `sstablerepairedset (page 401)`. To mark a single SSTable `SSTable-example-Data.db`:

   `sudo bin/sstablerepairedset --really-set --is-repaired SSTable-example-Data.db`

   To do this as a batch process using a text file of SSTable names:
sudo bin/sstablerepairedset --really-set --is-repaired -f SSTable-names.txt

**Note:** The value of the `repairedAt` metadata is the timestamp of the last repair. The `sstablerepairedset` command applies the current date/time. To check the value of the `repairedAt` metadata for an SSTable, use:

```bash
$ bin/sstablemetadata example-keyspace-SSTable-example-Data.db | grep "Repaired at"
```

5. Restart the node.

**What's next:**

After you have migrated all nodes, you will be able to run incremental repairs using `nodetool repair` with the `-inc` option. For details, see [https://www.datastax.com/dev/blog/more-efficient-repairs](https://www.datastax.com/dev/blog/more-efficient-repairs).

**Related information:**

## Monitoring Cassandra

### Getting statistics and metrics

Understanding the performance characteristics of a Cassandra cluster is critical to diagnosing issues and planning capacity. Use DataStax tools and a Java Console (JConsole) to get node and cluster statistics.

Cassandra exposes a number of statistics and management operations via Java Management Extensions (JMX). JMX is a Java technology that supplies tools for managing and monitoring Java applications and services. Any statistic or operation that a Java application has exposed as an MBean can then be monitored or manipulated using JMX.

JMX). JMX is a Java technology that supplies tools for managing and monitoring Java applications and services. Any statistic or operation that a Java application has exposed as an MBean can then be monitored or manipulated using JMX.

During normal operation, Cassandra outputs information and statistics that you can monitor using JMX-compliant tools, such as:

- The Cassandra `nodetool` utility *(page 250)*
- `nodetool sjk` *(page 333)*
- Using JConsole *(page 226)*
Using the same tools, you can perform certain administrative commands and operations such as flushing caches or doing a node repair (page 246).

Using nodetool

The nodetool utility (page 250) is a command-line interface for monitoring a cluster and performing routine database operations. It is typically run from an operational node.

The nodetool utility provides commands for viewing detailed metrics for tables, server metrics, and compaction statistics:

- **nodetool tablestats** (page 350) displays statistics for each table and keyspace.
- **nodetool tablehistograms** (page 348) provides statistics about a table, including read/write latency, row size, column count, and number of SSTables.
- **nodetool netstats** (page 300) provides statistics about network operations and connections.
- **nodetool tpstats** (page 358) provides statistics about the number of active, pending, and completed tasks for each stage of database operations by thread pool.

This example shows the output from nodetool proxyhistograms after running 4,500 insert statements and 45,000 select statements on a three ccm node-cluster on a local computer.

```
$ nodetool proxyhistograms

proxy histograms
Percentile Read Latency Write Latency Range Latency
(micros) (micros) (micros)
50% 1502.50 375.00 446.00
75% 1714.75 420.00 498.00
95% 31210.25 507.00 800.20
98% 36365.00 507.36 948.40
99% 36365.00 740.60 1024.39
Min 616.00 230.00 311.00
Max 36365.00 55726.00 59247.00
```

For a summary of the ring and its current state of general health, use nodetool status (page 341). For example:

```
$ nodetool status

Note: Ownership information does not include topology; for complete information, specify a keyspace
Datacenter: datacenter1
Status=Up/Down
|-- Address  Load  Tokens  Owns  Host ID
     Rack
```
Operations

Using JConsole

JConsole is a JMX-compliant tool for monitoring Java applications. JConsole is included with Sun JDK 5.0 and later. JConsole consumes the JMX metrics and operations exposed by DataStax Enterprise and displays them in a well-organized GUI. For each node monitored, JConsole provides these six separate tab views:

**Overview**
- Displays overview information about the Java VM and monitored values.

**Memory**
- Displays information about memory use.

**Threads**
- Displays information about thread use.

**Classes**
- Displays information about class loading.

**VM Summary**
- Displays information about the Java Virtual Machine (VM).

**Mbeans**
- Displays information about MBeans.

The Overview and Memory tabs contain information that is very useful for developers. The Memory tab allows you to compare heap and non-heap memory usage, and provides a control to immediately perform Java garbage collection.

For specific database metrics and operations, the most important area of JConsole is the MBeans tab. This tab lists the following MBeans:

- **org.apache.cassandra.auth**
  - Includes permissions cache.

- **org.apache.cassandra.db**
  - Includes caching, table metrics, and compaction.

- **org.apache.cassandra.internal**
  - Internal server operations such as gossip, hinted handoff, and Memtable values.

- **org.apache.cassandra.metrics**
  - Includes metrics on CQL, clients, keyspaces, read repair, storage, threadpools, and other topics.

- **org.apache.cassandra.net**
  - Inter-node communication including FailureDetector, MessagingService, and StreamingManager.

- **org.apache.cassandra.request**
  - Tasks related to read, write, and replication operations.

- **org.apache.cassandra.service**
Includes GCInspector.

When you select an MBean in the tree, its MBeanInfo and MBean Descriptor are displayed on the right, and any attributes, operations or notifications appear in the tree below it. For example, selecting and expanding the org.apache.cassandra.db MBean to view available actions for a table results in a display like the following:

If you choose to monitor DataStax Enterprise using JConsole, keep in mind that JConsole consumes a significant amount of system resources. For this reason, DataStax recommends running JConsole on a remote machine rather than on the same host as a DataStax Enterprise node.

The JConsole CompactionManagerMBean exposes compaction metrics (page 232) that can indicate when you need to add capacity to your cluster.

**Using nodetool sjk**

Nodetool includes the open source Swiss Java Knife as a built-in command, nodetool sjk (page 333), for troubleshooting. This section focuses on using the `mx` subcommand to get and set JMX MBean values.

**Attention:** The `nodetool sjk mxdump` command tries to print all exposed MBeans to the console. The command can fail if it encounters an improperly formatted MBean. To interact with a specific list of MBeans, use the `nodetool sjk mx` command.

**Listing MBean names**

To get values from the command line, first get the complete name of the MBean.

Following is an example of how to use `jmxterm` to dump the full list of JMX MBeans from a database node:
Operations

```bash
$ echo "beans" | java -jar jmxterm-1.0.0-uber.jar -l localhost:7199 -n 2>&1
```

**Tip:** Only perform this operation once because the list can be large or search MBeans with particular names in the output by redirecting the result to another filter. For example to find MBeans that contain the word commitlog:

```bash
$ echo "beans" | java -jar /tmp/jmxterm-1.0.0-uber.jar -l localhost:7199 -n 2>&1 | grep -i commitlog
```

The results provide the exact MBean strings to use in `nodetool s jk mx` command.

```plaintext
com.datastax.bdp.advrep.v2.metrics:name=CommitLogMessagesRead,type=ReplicationLog
com.datastax.bdp.advrep.v2.metrics:name=CommitLogsDeleted,type=ReplicationLog
com.datastax.bdp.advrep.v2.metrics:name=CommitLogsToConsume,type=ReplicationLog
org.apache.cassandra.db:type=Commitlog
org.apache.cassandra.metrics:name=CompletedTasks,type=CommitLog
org.apache.cassandra.metrics:name=PendingTasks,type=CommitLog
org.apache.cassandra.metrics:name=TotalCommitLogSize,type=CommitLog
org.apache.cassandra.metrics:name=WaitingOnCommit,type=CommitLog
org.apache.cassandra.metrics:name=WaitingOnSegmentAllocation,type=CommitLog
```

Getting the MBean options and values

Use the MBean information option to show available values. For example, to show the options available for `TotalCommitLogSize` from the previous results, use the complete name:

```bash
$ nodetool s jk mx -b
  "org.apache.cassandra.metrics:name=TotalCommitLogSize,type=CommitLog" -mi
```

```plaintext
org.apache.cassandra.metrics:type=CommitLog,name=TotalCommitLogSize
org.apache.cassandra.metrics.CassandraMetricsRegistry$JmxGauge
  - Information on the management interface of the MBean
  (A) Value : java.lang.Object
  - Attribute exposed for management
  (O) objectName() : javax.managementObjectName
  - Operation exposed for management
```

The MBean has a simple value. To read the single number, run the following command:

```bash
$ nodetool s jk mx -b
  "org.apache.cassandra.metrics:name=TotalCommitLogSize,type=CommitLog" -f Value -mg
```

```plaintext
org.apache.cassandra.metrics:type=CommitLog,name=TotalCommitLogSize
67108864
```
**Note:** SJK is case-sensitive, enter the names exactly.

To check on a more complex metric such as latency, find out how many values are available by using `-mi` option:

```bash
$ nodetool sjk mx -b
"org.apache.cassandra.metrics:name=Latency,scope=Read,type=ClientRequest"
-mi
```

```
org.apache.cassandra.metrics:type=ClientRequest,scope=Read,name=Latency
org.apache.cassandra.metrics.CassandraMetricsRegistry$JmxTimer
- Information on the management interface of the MBean

  (A) OneMinuteRate : double
  (A) FifteenMinuteRate : double
  (A) FiveMinuteRate : double
  (A) MeanRate : double
  (A) RateUnit : String
  (A) Count : long
  (O) values() : long[]
  (O) objectName() : javax.management.ObjectName
- Operation exposed for management
```

Then to read out a single value from this metric, use the following command:
Table statistics

For individual tables, ColumnFamilyStoreMBean provides the same general latency attributes as StorageProxyMBean. Unlike StorageProxyMBean, ColumnFamilyStoreMBean has a number of other statistics that are important to monitor for performance trends. The most important of these are:

Table 8: Table Statistics

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MemtableDataSize</td>
<td>The total size consumed by this table's data (not including metadata).</td>
</tr>
<tr>
<td>MemtableColumnsCount</td>
<td>Returns the total number of columns present in the memtable (across all keys).</td>
</tr>
<tr>
<td>MemtableSwitchCount</td>
<td>How many times the memtable has been flushed out.</td>
</tr>
<tr>
<td>RecentReadLatencyMicros</td>
<td>The average read latency since the last call to this bean.</td>
</tr>
<tr>
<td>RecentWriterLatencyMicros</td>
<td>The average write latency since the last call to this bean.</td>
</tr>
<tr>
<td>LiveSSTableCount</td>
<td>The number of live SSTables for this table.</td>
</tr>
</tbody>
</table>

The recent read latency and write latency counters are important in making sure operations are happening in a consistent manner. If these counters start to increase after a period of staying flat, you probably need to add capacity to the cluster.

You can set a threshold and monitor LiveSSTableCount to ensure that the number of SSTables (page) for a given table does not become too great.

Thread pool and read/write latency statistics

Cassandra maintains distinct thread pools for different stages of execution. Each of the thread pools provide statistics on the number of tasks that are active, pending, and completed. Trends on these pools for increases in the pending tasks column indicate when to add additional capacity. After a baseline is established, configure alarms for any increases above normal in the pending tasks column. Use nodetool tpstats (page 358) on the command line to view the thread pool details shown in the following table.
### Table 9: Thread Pool statistics reported by nodetool tpstats

<table>
<thead>
<tr>
<th>Thread Pool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AntiEntropyStage</td>
<td>Tasks related to repair</td>
</tr>
<tr>
<td>CacheCleanupExecutor</td>
<td>Tasks related to cache maintenance (counter cache, row cache)</td>
</tr>
<tr>
<td>CompactionExecutor</td>
<td>Tasks related to compaction</td>
</tr>
<tr>
<td>CounterMutationStage</td>
<td>Tasks related to leading counter writes</td>
</tr>
<tr>
<td>GossipStage</td>
<td>Tasks related to the gossip protocol</td>
</tr>
<tr>
<td>HintsDispatcher</td>
<td>Tasks related to sending hints</td>
</tr>
<tr>
<td>InternalResponseStage</td>
<td>Tasks related to miscellaneous internal task responses</td>
</tr>
<tr>
<td>MemtableFlushWriter</td>
<td>Tasks related to flushing memtables</td>
</tr>
<tr>
<td>MemtablePostFlush</td>
<td>Tasks related to maintenance after memtable flush completion</td>
</tr>
<tr>
<td>MemtableReclaimMemory</td>
<td>Tasks related to reclaiming memtable memory</td>
</tr>
<tr>
<td>MigrationStage</td>
<td>Tasks related to schema maintenance</td>
</tr>
<tr>
<td>MiscStage</td>
<td>Tasks related to miscellaneous tasks, including snapshots and removing hosts</td>
</tr>
<tr>
<td>MutationStage</td>
<td>Tasks related to writes</td>
</tr>
<tr>
<td>Native-Transport-Requests</td>
<td>Tasks related to client requests from CQL</td>
</tr>
<tr>
<td>PendingRangeCalculator</td>
<td>Tasks related to recalculating range ownership after bootstraps/decommissions</td>
</tr>
<tr>
<td>PerDiskMemtableFlushWriter</td>
<td>Tasks related to flushing memtables to a given disk</td>
</tr>
<tr>
<td>ReadRepairStage</td>
<td>Tasks related to performing read repairs</td>
</tr>
<tr>
<td>ReadStage</td>
<td>Tasks related to reads</td>
</tr>
<tr>
<td>RequestResponseStage</td>
<td>Tasks for callbacks from intra-node requests</td>
</tr>
<tr>
<td>Sampler</td>
<td>Tasks related to sampling statistics</td>
</tr>
<tr>
<td>SecondaryIndexManagement</td>
<td>Tasks related to secondary index maintenance</td>
</tr>
<tr>
<td>ValidationExecutor</td>
<td>Tasks related to validation compactions</td>
</tr>
<tr>
<td>ViewMutationStage</td>
<td>Tasks related to maintaining materialized views</td>
</tr>
</tbody>
</table>
Read/Write latency metrics

Cassandra tracks latency (averages and totals) of read, write, and slicing operations at the server level through StorageProxyMBean.

Compaction metrics

Monitoring compaction performance is an important aspect of knowing when to add capacity to your cluster. The following attributes are exposed through CompactionManagerMBean:

Table 10: Compaction Metrics

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BytesCompacted</td>
<td>Total number of bytes compacted since server [re]start</td>
</tr>
<tr>
<td>CompletedTasks</td>
<td>Number of completed compactions since server [re]start</td>
</tr>
<tr>
<td>PendingTasks</td>
<td>Estimated number of compactions remaining to perform</td>
</tr>
<tr>
<td>TotalCompleted</td>
<td>Total number of compactions since server [re]start</td>
</tr>
</tbody>
</table>

Tuning Java resources

Tuning the Java Virtual Machine (JVM) can improve performance or reduce high memory consumption.

Topics in this page:
- About garbage collection (page 232)
- Choosing a Java garbage collector (page 233)
- Setting G1 as the Java garbage collector (page 233)
- Determining the heap size (page 234)
- How Cassandra uses memory (page 235) - Read first for a better understanding of the settings and recommendations in this topic.
- Adjusting JVM parameters for other Cassandra services (page 236)
- Other JMX options (page 236)

About garbage collection

Garbage collection is the process by which Java removes data that is no longer needed from memory. To achieve the best performance, it is important to select the right garbage collector and heap size settings.

One situation that you definitely want to minimize is a garbage collection pause, also known as a stop-the-world event. A pause occurs when a region of memory is full and the JVM needs to make space to continue. During a pause all operations are suspended. Because a pause affects networking, the node can appear as down to other nodes in the cluster. Additionally, any Select and Insert statements will wait, which increases read and write latencies. Any pause of more than a second, or multiple pauses within a second that add
to a large fraction of that second, should be avoided. The basic cause of the problem is the rate of data stored in memory outpaces the rate at which data can be removed. For specific symptoms and causes, see Garbage collection pauses (page ).

Choosing a Java garbage collector

For Cassandra 3.0 and later, using the Concurrent-Mark-Sweep (CMS) or G1 garbage collector depends on these factors:

G1 is recommended in the following circumstances and reasons:

- Heap sizes from 16 GB to 64 GB.
  
  G1 performs better than CMS for larger heaps because it scans the regions of the heap containing the most garbage objects first, and compacts the heap on-the-go, while CMS stops the application when performing garbage collection.

- The workload is variable, that is, the cluster is performing the different processes all the time.
- For future proofing, as CMS will be deprecated in Java 9.
- G1 is easier to configure.
- G1 is self tuning.

CMS is recommended in the following circumstances:

- You have the time and expertise to manually tune and test garbage collection.
  
  Be aware that allocating more memory to the heap, can result in diminishing performance as the garbage collection facility increases the amount of Cassandra metadata in heap memory.

- Heap sizes no larger than 16 GB.
- The workload is fixed, that is, the cluster performs the same processes all the time.
- The environment requires the lowest latency possible. G1 incurs some latency due to profiling.

  Note: For help configuring CMS, contact the DataStax Services team.

Setting G1 as the Java garbage collector

1. Open jvm.options.

2. Comment out the -Xmn800M line.

3. Comment out all lines in the ### CMS Settings section.

4. Uncomment the relevant G1 settings in the ### G1 Settings section:

```java
## Use the Hotspot garbage-first collector.
-XX:+UseG1GC
#
## Have the JVM do less remembered set work during STW, instead
```
## preferring concurrent GC. Reduces p99.9 latency.

#-XX:G1RSetUpdatingPauseTimePercent=5

**Note:** When using G1, you only need to set MAX_HEAP_SIZE.

### Determining the heap size

You might be tempted to set the Java heap to consume the majority of the computer’s RAM. However, this can interfere with the operation of the OS page cache. Recent operating systems maintain the OS page cache for frequently accessed data and are very good at keeping this data in memory. Properly tuning the OS page cache usually results in better performance than increasing the Cassandra row cache.

Cassandra automatically calculates the maximum heap size (MAX_HEAP_SIZE) based on this formula:

```
max(min(1/2 ram, 1024MB), min(1/4 ram, 8GB))
```

For production use, you may wish to adjust heap size for your environment using the following guidelines:

- Heap size is usually between ¼ and ½ of system memory.
- Do not devote all memory to heap because it is also used for offheap cache and file system cache.
- Always enable GC logging when adjusting GC.
- Adjust settings gradually and test each incremental change.
- Enable parallel processing for GC, particularly when using DSE Search.
- Cassandra’s GCInspector class logs information about any garbage collection that takes longer than 200 ms. Garbage collections that occur frequently and take a moderate length of time (seconds) to complete, indicate excessive garbage collection pressure on the JVM. In addition to adjusting the garbage collection options, other remedies include adding nodes, and lowering cache sizes.
- For a node using G1, the Cassandra community recommends a MAX_HEAP_SIZE as large as possible, up to 64 GB.

**Note:** For more tuning tips, see [Secret HotSpot option improving GC pauses on large heaps](#).

### MAX_HEAP_SIZE

The recommended maximum heap size depends on which GC is used:

<table>
<thead>
<tr>
<th>Hardware setup</th>
<th>Recommended MAX_HEAP_SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Older computers</td>
<td>Typically 8 GB.</td>
</tr>
<tr>
<td>CMS for newer computers (8+ cores) with up to 256 GB RAM</td>
<td>No more 16 GB.</td>
</tr>
</tbody>
</table>
The easiest way to determine the optimum heap size for your environment is:

1. Set the maximum heap size in the `jvm.options` file to a high arbitrary value on a single node. For example, when using G1:
   
   ```
   -Xms48G
   -Xmx48G
   ```

   Set the min (`-Xms`) and max (`-Xmx`) heap sizes to the same value to avoid stop-the-world GC pauses during resize, and to lock the heap in memory on startup which prevents any of it from being swapped out.

2. Enable GC logging.

3. Check the logs to view the heap used by that node and use that value for setting the heap size in the cluster:

   **Note:** This method decreases performance for the test node, but generally does not significantly reduce cluster performance.

If you don’t see improved performance, contact the DataStax Services team for additional help.

**HEAP_NEWSIZE**

For CMS, you may also need to adjust HEAP_NEWSIZE. This setting determines the amount of heap memory allocated to newer objects or young generation. Cassandra calculates the default value for this property (in MB) as the lesser of:

- 100 times the number of cores
- ¼ of MAX_HEAP_SIZE

As a starting point, set HEAP_NEWSIZE to 100 MB per physical CPU core. For example, for a modern 8-core+ machine:

```
-Xmn800M
```

A larger HEAP_NEWSIZE leads to longer GC pause times. For a smaller HEAP_NEWSIZE, GC pauses are shorter but usually more expensive.

How Cassandra uses memory

Cassandra performs the following major operations within JVM heap:

- To perform reads, Cassandra maintains the following components in heap memory:
Operations

# Bloom filters
# Partition summary
# Partition key cache
# Compression offsets
# SSTable index summary

This metadata resides in memory and is proportional to total data. Some of the components grow proportionally to the size of total memory (page 52).

- Cassandra gathers replicas for a read or for anti-entropy repair and compares the replicas in heap memory.
- Data written to Cassandra is first stored in memtables in heap memory. Memtables are flushed to SSTables on disk.

To improve performance, Cassandra also uses off-heap memory as follows:

- Page cache. Cassandra uses additional memory as page cache when reading files on disk.
- The Bloom filter and compression offset maps reside off-heap.
- Cassandra can store cached rows in native memory, outside the Java heap. This reduces JVM heap requirements, which helps keep the heap size in the sweet spot for JVM garbage collection performance.

Adjusting JVM parameters for other Cassandra services

- **Solr**: Some Solr users have reported that increasing the stack size improves performance under Tomcat.

  To increase the stack size, uncomment and modify the default setting in the cassandra-env.sh file.

  ```
  # Per-thread stack size.
  JVM_OPTS="$JVM_OPTS -Xss256k"
  ```

  Also, decreasing the memtable space to make room for Solr caches can improve performance. Modify the memtable space by changing the `memtable_heap_space_in_mb (page 94)` and `memtable_offheap_space_in_mb (page 94)` properties in the cassandra.yaml file.

- **MapReduce**: Because MapReduce runs outside the JVM, changes to the JVM do not affect Analytics/Hadoop operations directly.

Other JMX options

Cassandra exposes other statistics and management operations via Java Management Extensions (JMX). **JConsole (page 226)** and the **nodetool (page 250)** utility are JMX-compliant management tools.

Configure Cassandra for JMX management by editing these properties in cassandra-env.sh.
• `com.sun.management.jmxremote.port`: sets the port on which Cassandra listens from JMX connections.
• `com.sun.management.jmxremote.ssl`: enables or disables SSL for JMX.
• `com.sun.management.jmxremote.authenticate`: enables or disables remote authentication for JMX.
• `-Djava.rmi.server.hostname`: sets the interface hostname or IP that JMX should use to connect. Uncomment and set if you are having trouble connecting.

**Note:** By default, you can interact with Cassandra using JMX on port 7199 without authentication.

The location of the `cassandra.yaml` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
</tbody>
</table>

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra-env.sh</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra-env.sh</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra-env.sh</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/conf/cassandra-env.sh</code></td>
</tr>
</tbody>
</table>

The location of the `jvm.options` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/jvm.options</code></td>
</tr>

<td><code>install_location/resources/cassandra/conf/jvm.options</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/jvm.options</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/conf/jvm.options</code></td>
</tr>
</tbody>
</table>

**Data caching**

**Configuring data caches**

Cassandra includes integrated caching and distributes cache data around the cluster. When a node goes down, the client can read from another cached replica of the data. The integrated architecture also facilitates troubleshooting because there is no separate caching tier, and cached data matches what is in the database exactly. The integrated cache alleviates the cold start problem by saving the cache to disk periodically. Cassandra reads
contents back into the cache and distributes the data when it restarts. The cluster does not start with a cold cache.

The saved key cache files include the ID of the table in the file name. A saved key cache filename for the users table in the mykeyspace keyspace looks similar to: `mykeyspace-users.users_name_idx-19bd7f80352c11e4aa6a57448213f97f-KeyCache-b.db2046071785672832311.tmp`

About the partition key cache

The partition key cache is a cache of the partition index (page 102) for a Cassandra table. Using the key cache instead of relying on the OS page cache decreases seek times. Enabling just the key cache results in disk (or OS page cache) activity to actually read the requested data rows, but not enabling the key cache results in more reads from disk.

About the row cache

Note: Utilizing appropriate OS page cache will result in better performance than using row caching. Consult resources for page caching for the operating system on which Cassandra is hosted.

Configure the number of rows to cache in a partition by setting the rows_per_partition table option. To cache rows, if the row key is not already in the cache, Cassandra reads the first portion of the partition, and puts the data in the cache. If the newly cached data does not include all cells configured by user, Cassandra performs another read. The actual size of the row-cache depends on the workload. You should properly benchmark your application to get "the best" row cache size to configure.

There are two row cache options, the old serializing cache provider and a new off-heap cache (OHC) provider. The new OHC provider has been benchmarked as performing about 15% better than the older option.

Using key cache and row cache

Typically, you enable either the partition key or row cache for a table.

Tip: Enable a row cache only when the number of reads is much bigger (rule of thumb is 95%) than the number of writes. Consider using the operating system page cache instead of the row cache, because writes to a partition invalidate the whole partition in the cache.

Tip: Disable caching entirely for archive tables, which are infrequently read.

Enabling and configuring caching

Use CQL to enable or disable caching by configuring the caching table property (page 102). Set parameters in the cassandra.yaml file to configure global caching properties:

- Partition key cache size (page 102)
- Row cache size (page 103)
- How often Cassandra saves partition key caches (page 102) to disk
An image is shown of a page from a document discussing Cassandra operations.

- How often Cassandra saves row caches (page 103) to disk

Configuring the `row_cache_size_in_mb` (in the `cassandra.yaml` (page 103) configuration file) determines how much space in memory Cassandra allocates to store rows from the most frequently read partitions of the table.

The location of the `cassandra.yaml` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Cassandra.yaml Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
</tbody>
</table>

1. Set the table caching property that configures the partition key cache and the row cache.

```sql
CREATE TABLE users (
    userid text PRIMARY KEY,
    first_name text,
    last_name text,
) WITH caching = ( 'keys' : 'NONE', 'rows_per_partition' : '120' );
```

**Tips for efficient cache use**

Tuning the row cache in Cassandra 2.1 describes best practices of using the built-in caching mechanisms and designing an effective data model. Some tips for efficient cache use are:

- Store lower-demand data or data with extremely long partitions in a table with minimal or no caching.
- Deploy a large number of Cassandra nodes under a relatively light load per node.
- Logically separate heavily-read data into discrete tables.

When you query a table, turn on tracing (page) to check that the table actually gets data from the cache rather than from disk. The first time you read data from a partition, the trace shows this line below the query because the cache has not been populated yet:

```
Row cache miss [ReadStage:41]
```

In subsequent queries for the same partition, look for a line in the trace that looks something like this:

```
Row cache hit [ReadStage:55]
```

This output means the data was found in the cache and no disk read occurred. Updates invalidate the cache. If you query rows in the cache plus uncached rows, request more...
rows than the global limit allows, or the query does not grab the beginning of the partition, the trace might include a line that looks something like this:

```
Ignoring row cache as cached value could not satisfy query
[ReadStage:89]
```

This output indicates that an insufficient cache caused a disk read. Requesting rows not at the beginning of the partition is a likely cause. Try removing constraints that might cause the query to skip the beginning of the partition, or place a limit (page ... ) on the query to prevent results from overflowing the cache. To ensure that the query hits the cache, try increasing the cache size limit, or restructure the table to position frequently accessed rows at the head of the partition.

**Monitoring and adjusting caching**

Make changes to cache options in small, incremental adjustments, then monitor the effects of each change using the `nodetool utility (page 250)`. The output of the `nodetool info` command shows the following row cache and key cache setting values, which are configured in the `cassandra.yaml` file:

- Cache size in bytes
- Capacity in bytes
- Number of hits
- Number of requests
- Recent hit rate
- Duration in seconds after which Cassandra saves the key cache.

For example, on start-up, the information from `nodetool info` might look something like this:

```
ID               : 387d15ba-7103-491b-9327-1a691dbb504a
Gossip active    : true
Thrift active    : true
Native Transport active: true
Load             : 65.87 KB
Generation No    : 1400189757
Uptime (seconds) : 148760
Heap Memory (MB) : 392.82 / 1996.81
datacenter      : datacenter1
Rack             : rack1
Exceptions       : 0
Key Cache        : entries 10, size 728 (bytes), capacity 103809024 (bytes), 93 hits, 102 requests, 0.912 recent hit rate, 14400 save period in seconds
Row Cache        : entries 0, size 0 (bytes), capacity 0 (bytes), 0 hits, 0 requests, NaN recent hit rate, 0 save period in seconds
Counter Cache    : entries 0, size 0 (bytes), capacity 51380224 (bytes), 0 hits, 0 requests, NaN recent hit rate, 7200 save period in seconds
Token            : -9223372036854775808
```
In the event of high memory consumption, consider tuning data caches.

The location of the *cassandra.yaml* file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

**Configuring memtable thresholds**

Configuring memtable thresholds can improve write performance. Cassandra flushes memtables to disk, creating SSTables when the commit log space threshold (page 96) or the memtable cleanup threshold (page 97) has been exceeded. Configure the commit log space threshold per node in the *cassandra.yaml*. How you tune memtable thresholds depends on your data and write load. Increase memtable thresholds under either of these conditions:

- The write load includes a high volume of updates on a smaller set of data.
- A steady stream of continuous writes occurs. This action leads to more efficient compaction.

Allocating memory for memtables reduces the memory available for caching and other internal Cassandra structures, so tune carefully and in small increments.

The location of the *cassandra.yaml* file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

**Configuring compaction**

As discussed in the Compaction (page 41) topic, the compaction process merges keys, combines columns, evicts tombstones, consolidates SSTables, and creates a new index in the merged SSTable.

In the *cassandra.yaml* file, you configure these global compaction parameters:

- `snapshot_before_compaction` (page 95)
- `concurrent_compactors` (page 97)
- `compaction_throughput_mb_per_sec` (page 93)
The `compaction_throughput_mb_per_sec` parameter is designed for use with large partitions. Cassandra throttles compaction to this rate across the entire system.

Cassandra provides a start-up option for testing compaction strategies (page 245) without affecting the production workload.

Cassandra supports the following compaction strategies, which you can configure using CQL:

- **LeveledCompactionStrategy (LCS)**: The leveled compaction strategy creates SSTables of a fixed, relatively small size (160 MB by default) that are grouped into levels. Within each level, SSTables are guaranteed to be non-overlapping. Each level (L0, L1, L2 and so on) is 10 times as large as the previous. Disk I/O is more uniform and predictable on higher than on lower levels as SSTables are continuously being compacted into progressively larger levels. At each level, row keys are merged into non-overlapping SSTables in the next level. This process can improve performance for reads, because Cassandra can determine which SSTables in each level to check for the existence of row key data. This compaction strategy is modeled after Google's LevelDB implementation. Also see LCS compaction subproperties (page ).

- **SizeTieredCompactionStrategy (STCS)**: The default compaction strategy. This strategy triggers a minor compaction when there are a number of similar sized SSTables on disk as configured by the table subproperty, `min_threshold`. A minor compaction does not involve all the tables in a keyspace. Also see STCS compaction subproperties (page ).

- **TimeWindowCompactionStrategy (TWCS)**: This strategy is an alternative for time series data. TWCS compacts SSTables using a series of time windows. While with a time window, TWCS compacts all SSTables flushed from memory into larger SSTables using STCS. At the end of the time window, all of these SSTables are compacted into a single SSTable. Then the next time window starts and the process repeats. The duration of the time window is the only setting required. See TWCS compaction subproperties (page ). For more information about TWCS, see How is data maintained? (page 40).

- **DateTieredCompactionStrategy (DTCS)**: This strategy is an alternative for time series data. It is deprecated in Cassandra 3.0.8/3.8 and later. DTCS stores data written within a certain period of time in the same SSTable. For example, Cassandra stores the last hour of data in one SSTable time window, and the next 4 hours of data in another time window, and so on. Compactions are triggered when the `min_threshold` (4 by default) for SSTables in those windows is reached. The most common queries for time series workloads retrieve the last hour/day/month of data. Cassandra can limit SSTables returned to those having the relevant data. Also, Cassandra can store data that has been set to expire using TTL in an SSTable with other data scheduled to expire at approximately the same time. Cassandra can then drop the SSTable without doing any compaction. Also see DTCS compaction subproperties (page ).

To configure the compaction strategy property and CQL compaction subproperties (page ), such as the maximum number of SSTables to compact and minimum SSTable size, use `CREATE TABLE` (page ) or `ALTER TABLE` (page ).

The location of the `cassandra.yaml` (page ) file depends on the type of installation:
1. Update a table to set the compaction strategy using the ALTER TABLE statement.

```
ALTER TABLE users WITH
    compaction = { 'class' : 'LeveledCompactionStrategy' }
```

2. Change the `compaction strategy property (page 232)` to SizeTieredCompactionStrategy and specify the minimum number of SSTables to trigger a compaction using the CQL `min_threshold` attribute.

```
ALTER TABLE users
    WITH compaction =
        { 'class' : 'SizeTieredCompactionStrategy', 'min_threshold' : 6 }
```

You can monitor the results of your configuration using compaction metrics, see Compaction metrics (page 232).

**What's next:** Cassandra 3.0 and later support extended logging for Compaction. This utility must be configured as part of the table configuration. The extended compaction logs are stored in a separate file. For details, see Enabling extended compaction logging (page 232).

## Compression

Compression maximizes the storage capacity of Cassandra nodes by reducing the volume of data on disk and disk I/O, particularly for read-dominated workloads. Cassandra quickly finds the location of rows in the SSTable index and decompresses the relevant row chunks. Compression is important for Cassandra 2.2, but Cassandra 3.0 and later uses a new storage engine that dramatically reduces disk volume automatically. For information on the Cassandra 3.0 improvements, see Putting some structure in the storage engine

Write performance is not negatively impacted by compression in Cassandra as it is in traditional databases. In traditional relational databases, writes require overwrites to existing data files on disk. The database has to locate the relevant pages on disk, decompress them, overwrite the relevant data, and finally recompress. In a relational database, compression is an expensive operation in terms of CPU cycles and disk I/O. Because Cassandra SSTable data files are immutable (they are not written to again after they have been flushed to disk), there is no recompression cycle necessary in order to process writes. SSTables are compressed only once when they are written to disk. Writes on compressed tables can show up to a 10 percent performance improvement.
In Cassandra 2.2 and later, the commit log can also be compressed and write performance can be improved 6-12%. For more information, see Updates to Cassandra’s Commit Log in 2.2.

**When to compress data**

Compression is most effective on a table with many rows, where each row contains the same set of columns (or the same number of columns) as all other rows. For example, a table containing user data such as `username`, `email` and `state` is a good candidate for compression. The greater the similarity of the data across rows, the greater the compression ratio and gain in read performance.

A table whose rows contain differing sets of columns is not well-suited for compression.

Don't confuse table compression with compact storage (page 364) of columns, which is used for backward compatibility of old applications with CQL.

Depending on the data characteristics of the table, compressing its data can result in:

- 25-33% reduction in data size
- 25-35% performance improvement on reads
- 5-10% performance improvement on writes

After configuring compression on an existing table, subsequently created SSTables are compressed. Existing SSTables on disk are not compressed immediately. Cassandra compresses existing SSTables when the normal Cassandra compaction process occurs. Force existing SSTables to be rewritten and compressed by using `nodetool upgradesstables` (Cassandra 1.0.4 or later) or `nodetool scrub` (page 320).

**Configuring compression**

You configure a table property and subproperties to manage compression. The CQL table properties documentation (page 364) describes the types of compression options that are available. Compression is enabled by default.

1. Disable compression, using CQL to set the compression parameter `enabled` to `false`.

```cql
CREATE TABLE DogTypes (
    block_id uuid,
    species text,
    alias text,
    population varint,
    PRIMARY KEY (block_id)
) WITH compression = { 'enabled' : false };
```

2. Enable compression on an existing table, using ALTER TABLE to set the compression algorithm class to LZ4Compressor (Cassandra 1.2.2 and later), SnappyCompressor, or DeflateCompressor.
CREATE TABLE DogTypes (  
   block_id uuid,  
   species text,  
   alias text,  
   population varint,  
   PRIMARY KEY (block_id)  
);  
WITH compression = { 'class' : 'LZ4Compressor' };

3. Change compression on an existing table, using ALTER TABLE and setting the compression algorithm class to DeflateCompressor.

ALTER TABLE CatTypes  
WITH compression = { 'class' : 'DeflateCompressor',  
   'chunk_length_in_kb' : 64 };

You tune data compression on a per-table basis using CQL to alter a table.

Testing compaction and compression

Write survey mode is a Cassandra startup option for testing new compaction and compression strategies. In write survey mode, you can test out new compaction and compression strategies on that node and benchmark the write performance differences, without affecting the production cluster.

Write survey mode adds a node to a database cluster. The node accepts all write traffic as if it were part of the normal Cassandra cluster, but the node does not officially join the ring.

Also use write survey mode to try out a new Cassandra version. The nodes you add in write survey mode to a cluster must be of the same major release version as other nodes in the cluster. The write survey mode relies on the streaming subsystem that transfers data between nodes in bulk and differs from one major release to another.

If you want to see how read performance is affected by modifications, stop the node, bring it up as a standalone machine, and then benchmark read operations on the node.

1. Start the Cassandra node using the write_survey option:
   • Cassandra package installations: Add the following option to cassandra-env.sh file:

   ```bash
   JVM_OPTS="$JVM_OPTS -Dcassandra.write_survey=true"
   ```

   • Cassandra tarball installations: Start Cassandra with this option:

   ```bash
   cd install_location
   $ sudo bin/dse cassandra -Dcassandra.write_survey=true #Starts DataStax Enterprise
   ```

   The location of the cassandra-topology.properties file depends on the type of installation:
The location of the cassandra-env.sh file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

Tuning Bloom filters

Cassandra uses Bloom filters to determine whether an SSTable has data for a particular partition. Bloom filters are unused for range scans, but are used for index scans. Bloom filters are probabilistic sets that allow you to trade memory for accuracy. This means that higher Bloom filter attribute settings `bloom_filter_fp_chance` use less memory, but will result in more disk I/O if the SSTables are highly fragmented. Bloom filter settings range from 0 to 1.0 (disabled). The default value of `bloom_filter_fp_chance` depends on the compaction strategy. The LeveledCompactionStrategy uses a higher default value (0.1) than the SizeTieredCompactionStrategy or DateTieredCompactionStrategy, which have a default of 0.01. Memory savings are nonlinear; going from 0.01 to 0.1 saves about one third of the memory. SSTables using LCS contain a relatively smaller ranges of keys than those using STCS, which facilitates efficient exclusion of the SSTables even without a bloom filter; however, adding a small bloom filter helps when there are many levels in LCS.

The settings you choose depend on the type of workload. For example, to run an analytics application that heavily scans a particular table, you would want to inhibit the Bloom filter on the table by setting it high.

To view the observed Bloom filters false positive rate and the number of SSTables consulted per read use `tablestats` in the nodetool utility.

Bloom filters are stored off-heap so you don’t need include it when determining the `-Xmx` settings (the maximum memory size that the heap can reach for the JVM).

To change the `bloom filter property` on a table, use CQL. For example:
After updating the value of `bloom_filter_fp_chance` on a table, Bloom filters need to be regenerated in one of these ways:

- Initiate compaction (page 241)
- Upgrade SSTables (page 364)

You do not have to restart Cassandra after regenerating SSTables.

## Moving data to or from other databases

Cassandra offers several solutions for migrating from other databases:

- The **COPY command** (page 260), which mirrors what the PostgreSQL RDBMS uses for file/export import.
- The **Cassandra bulk loader** (page 388) provides the ability to bulk load external data into a cluster.

### About the COPY command

You can use COPY in CQL shell to load flat file data into Cassandra (nearly all relational databases have unload utilities that allow table data to be written to OS files) as well to write Cassandra data to CSV files.

### ETL Tools

If you need more sophistication applied to a data movement situation (more than just extract-load), then you can use any number of extract-transform-load (ETL) solutions that now support Cassandra. These tools provide excellent transformation routines that allow you to manipulate source data in literally any way you need and then load it into a Cassandra target. They also supply many other features such as visual, point-and-click interfaces, scheduling engines, and more.

Many ETL vendors who support Cassandra supply community editions of their products that are free and able to solve many different use cases. Enterprise editions are also available that supply many other compelling features that serious enterprise data users need.

You can freely download and try ETL tools from Jaspersoft, Pentaho, and Talend that all work with Cassandra.

## Purging gossip state on a node

Gossip information is persisted locally by each node to use immediately on node restart without having to wait for gossip communications.

In the unlikely event you need to correct a problem in the gossip state:

1. Use the **nodetool assassinate** (page 252) to shut down the problem node.
Operations

This takes approximately 35 seconds to complete, so wait for confirmation that the node is deleted.

2. If this method doesn't solve the problem, stop your client application from sending writes to the cluster.

3. Take the entire cluster offline:
   a. Drain ([page 272]) each node.
      
      $ nodetool options drain
   
   b. Stop each node:
      
      • Cassandra package installations:
        
        $ sudo service dse stop #Stop DataStax Enterprise
      
      • Cassandra tarball installations:
        
        $ sudo service dse stop #Stop DataStax Enterprise

4. Clear the data from the peers directory, remove all directories in the peers-UUID directory, where UUID is the particular directory that corresponds to the appropriate node:

   $ sudo rm -r /var/lib/cassandra/data/system/peers-UUID/*

   **Caution:**

   Use caution when performing this step. The action clears internal system data from Cassandra and may cause application outage without careful execution and validation of the results. To validate the results, run the following query individually on each node to confirm that all of the nodes are able to see all other nodes.

   select * from system.peers;

5. Clear the gossip state when the node starts:

   • For tarball installations, you can use a command line option or edit the cassandra-env.sh. To use the command line:

     $ install_location/bin/dse cassandra -
     Dcassandra.load_ring_state=false #Starts DataStax Enterprise

   • For package installations or if you are not using the command line option above ([page 248]), add the following line to the cassandra-env.sh file:
JVM_OPTS="$JVM_OPTS -Dcassandra.load_ring_state=false"

# Cassandra package installations: /usr/share/cassandra/cassandra-env.sh
# Cassandra tarball installations: install_location/conf/cassandra-env.sh

The location of the cassandra-env.sh file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

6. Bring the cluster online one node at a time, starting with the seed nodes.
   - Cassandra package installations:
     
     $ sudo service dse start #Starts DataStax Enterprise #Starts DataStax Enterprise
     
   - Cassandra tarball installations:
     
     $ cd install_location
     $ bin/dse cassandra #Starts DataStax Enterprise

What's next:
Remove the line you added in the cassandra-env.sh file.
Cassandra tools

The nodetool utility

About the nodetool utility

The nodetool utility is a command line interface for managing a cluster.

Command formats

$ nodetool [options] command [args]

installation_location/resources/cassandra/bin

- Cassandra package installations: /etc/cassandra
- Cassandra tarball installations: install_location/conf
- DataStax Enterprise package installations: /etc/dse/cassandra
- DataStax Enterprise tarball installations: install_location/resources/cassandra/conf

Main options

The following options apply to all nodetool commands:

**Table 11: Main options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Username.</td>
</tr>
<tr>
<td></td>
<td>--</td>
<td>Separates command parameters from a list of options.</td>
</tr>
</tbody>
</table>

**Note:**

- If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.

The location of the cassandra-env.sh file depends on the type of installation:
Cassandra tools

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>
<th>/etc/dse/cassandra/cassandra-env.sh</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

- The repair and rebuild commands can affect multiple nodes in the cluster.
- Most nodetool commands operate on a single node in the cluster if `-h` is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the `-h` option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using `-h`.

Example:

```
$ nodetool -u username -pw password command command_options
```

Using nodetool command help

- `nodetool help`
  Provides a listing of nodetool commands.
- `nodetool help command`
  Provides help on a specific command. For example:

```
$ nodetool help upgradesstables
```

For more information, see `nodetool help (page 290)`

**nodetool abortrebuild**

Abort a currently running rebuild operation that was started on the connected node. Completes processing of active streams, but no new streams are started. The abort operation is logged with an optional reason comment.

**Synopsis**

```
nodetool connection_options abortrebuild [-r 'log_comment']
```

**Main options**

The following options apply to all nodetool commands:

**Table 12: Main options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
</tbody>
</table>
Cassandra tools

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Username.</td>
</tr>
<tr>
<td></td>
<td>--</td>
<td>Separates command parameters from a list of options.</td>
</tr>
</tbody>
</table>

**Note:**

- If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.

The location of the cassandra-env.sh file depends on the type of installation:

| DataStax Enterprise 5.0 Installer-Services and package installations | /etc/dse/cassandra/cassandra-env.sh |
| DataStax Enterprise 5.0 Installer-No Services and tarball installations | install_location/resources/cassandra/conf/cassandra-env.sh |
| Cassandra package installations                                      | /etc/cassandra/cassandra-env.sh    |
| Cassandra tarball installations                                      | install_location/conf/cassandra-env.sh |

- The repair and rebuild commands can affect multiple nodes in the cluster.
- Most nodetool commands operate on a single node in the cluster if -h is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the -h option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using -h.

**Example:**

```
$ nodetool -u username -pw password command command_options
```

- r 'log_comment', --reason 'log_comment'
  Comment added to log.

**nodetool assassinate**

Forcefully removes a dead node without re-replicating any data. It is a last resort tool if you cannot successfully use nodetool removenode (page 309).

**Synopsis**

```
$ nodetool [options] assassinate <ip_address>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:
**Table 13: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>ip_address</td>
<td></td>
<td>IP address of the endpoint to assassinate.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

**Note:**
- For tarball installations, execute the command from the `install_location/bin` directory.
- If a username and password for RMI authentication are set explicitly in the `cassandra-env.sh` file for the host, then you must specify credentials.
- `nodetool assassinate` operates on a single node in the cluster if `-h` is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the `-h` option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using `-h`.

**Description**

The `nodetool assassinate` command is a tool of last resort. Only use this tool to remove a node from a cluster when `removenode` is not successful.

**Examples**

```bash
$ nodetool -u cassandra -pw cassandra assassinate 192.168.100.2
```

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>File Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra-env.sh</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra-env.sh</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra-env.sh</code></td>
</tr>
</tbody>
</table>
nodetool bootstrap

Manage a node’s bootstrap process.

Synopsis

$ nodetool [options] bootstrap [resume]

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

/credentials/cassandra/bin

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

Note:

- For tarball installations, execute the command from the install_location/bin directory.
- If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.
- nodetool bootstrap operates on a single node in the cluster if -h is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the -h option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using -h.

Description

The nodetool bootstrap command can be used to manage a node’s bootstrap process. If no argument is defined, the help information is displayed. If the argument resume is used, bootstrap streaming is resumed.
Examples

$ nodetool -u cassandra -pw cassandra bootstrap resume

The location of the cassandra-env.sh file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td>/etc/dse/cassandra/cassandra-env.sh</td>

<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

nodetool cfhistograms

This tool has been renamed as nodetool tablehistograms (page 348).

nodetool cfstats

This tool has been renamed as nodetool tablestats (page 350).

nodetool cleanup

Cleans up keyspaces and partition keys no longer belonging to a node.

Synopsis

$ nodetool options cleanup [keyspace_name [table_name] [...]]

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

Table 15: Options

<table>
<thead>
<tr>
<th>Short</th>

<td>One or more table names, separated by a space.</td>
<td></td>
</tr>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

Description

Use this command to remove unwanted data after adding a new node to the cluster. Cassandra does not automatically remove data from nodes that lose part of their partition range to a newly added node. Run `nodetool cleanup` on the source node and on neighboring nodes that shared the same subrange after the new node is up and running. Failure to run this command after adding a node causes Cassandra to include the old data to rebalance the load on that node. Running the `nodetool cleanup` command causes a temporary increase in disk space usage proportional to the size of your largest SSTable. Disk I/O occurs when running this command.

Optionally, this command takes a list of table names. If you do not specify a keyspace, this command cleans all keyspaces no longer belonging to a node.

**nodetool clearsnapshot**

Removes one or more snapshots.

Synopsis

```
$ nodetool <options> clearsnapshot -t <snapshot> -- <keyspace> ...
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

**Table 16: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>

<td>Remove the snapshot with a designated name.</td>
<td></td>
</tr>
<tr>
<td><strong>keyspace</strong></td>
<td>Remove snapshots from the designated keyspaces, separated by a space.</td>
<td></td>
</tr>
</tbody>
</table>
### Description

Deletes snapshots in one or more keyspaces. To remove all snapshots, omit the snapshot name.

**nodetool compact**

Forces a major compaction (*page*) on one or more tables.

### Synopsis

```
$ nodetool [options] compact [(-et <end_token> | --end-token <end_token>)]
[(--s | --split-output)] [(-st <start_token> | --start-token <start_token>)] [--] [keyspace] [tables]... [--user-defined] <SSTable file>...
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

### Common options

These options apply to all nodetool commands.

#### Table 17: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Remote JMX agent port number.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent user name.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

**Note:**
For tarball installations, execute the command from the `installation_location/bin` directory.

If a username and password for RMI authentication are set explicitly in the `cassandra-env.sh` file for the host, then you must specify credentials.

Compact options

The following options are specific to the compact command:

**Table 18: compact options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-et token</code></td>
<td><code>--end-token token</code></td>
<td>Specify a token at which the compaction range ends. Requires start token (<code>-st</code>).</td>
</tr>
<tr>
<td><code>-st token</code></td>
<td><code>--start-token token</code></td>
<td>Specify a token at which the compaction range starts. Requires end token (<code>-et</code>).</td>
</tr>
<tr>
<td><code>-s</code></td>
<td><code>--split-output</code></td>
<td>Split output when using STCS to files that are 50%-25%-12.5% and so on of the total size.</td>
</tr>
</tbody>
</table>

**Note:**
- For STCS, excluding the `-s` option creates a single large SSTable.
- For DTCS, using `-s` has no effect; a single file is still created.

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>keyspace [tables]</td>
<td></td>
<td>Run compaction on an entire keyspace or specified tables; use a space to separate table names.</td>
</tr>
<tr>
<td><code>--user-defined sstable filenames</code></td>
<td></td>
<td>Run compaction on one or more SStables, specify the filenames.</td>
</tr>
</tbody>
</table>

**Description**

This command starts the compaction process on tables using SizeTieredCompactionStrategy (STCS), TimeWindowCompactionStrategy (TWCS), or Leveled compaction (LCS):

- If you do not specify a keyspace or table, a major compaction is run on all keyspaces and tables.
- If you specify only a keyspace, a major compaction is run on all tables in that keyspace.
- If you specify one or more tables, a major compaction is run on those tables.
Major compactions may behave differently depending which compaction strategy is used for the affected tables:

- **SizeTieredCompactionStrategy (STCS)**: The default compaction strategy. This strategy triggers a minor compaction when there are a number of similar sized SSTables on disk as configured by the table subproperty, `min_threshold`. A minor compaction does not involve all the tables in a keyspace. Also see STCS compaction subproperties (page 222).

- **DateTieredCompactionStrategy (DTCS)**: This strategy is an alternative for time series data. It is deprecated in Cassandra 3.0.8/3.8 and later. DTCS stores data written within a certain period of time in the same SSTable. For example, Cassandra stores the last hour of data in one SSTable *time window*, and the next 4 hours of data in another time window, and so on. Compactions are triggered when the `min_threshold` (4 by default) for SSTables in those windows is reached. The most common queries for time series workloads retrieve the last hour/day/month of data. Cassandra can limit SSTables returned to those having the relevant data. Also, Cassandra can store data that has been set to expire using TTL in an SSTable with other data scheduled to expire at approximately the same time. Cassandra can then drop the SSTable without doing any compaction. Also see DTCS compaction subproperties (page 422). (deprecated)

- **TimeWindowCompactionStrategy (TWCS)** This strategy is an alternative for time series data. TWCS compacts SSTables using a series of *time windows*. While with a time window, TWCS compacts all SSTables flushed from memory into larger SSTables using STCS. At the end of the time window, all of these SSTables are compacted into a single SSTable. Then the next time window starts and the process repeats. The duration of the time window is the only setting required. See TWCS compaction subproperties (page ). For more information about TWCS, see How is data maintained? (page 40).

- **LeveledCompactionStrategy (LCS)**: The leveled compaction strategy creates SSTables of a fixed, relatively small size (160 MB by default) that are grouped into levels. Within each level, SSTables are guaranteed to be non-overlapping. Each level (L0, L1, L2 and so on) is 10 times as large as the previous. Disk I/O is more uniform and predictable on higher than on lower levels as SSTables are continuously being compacted into progressively larger levels. At each level, row keys are merged into non-overlapping SSTables in the next level. This process can improve performance for reads, because Cassandra can determine which SSTables in each level to check for the existence of row key data. This compaction strategy is modeled after Google’s LevelDB implementation. Also see LCS compaction subproperties (page ).

For more details, see How is data maintained? (page ) and Configuring compaction (page 241).

**Note:** A major compaction incurs considerably more disk I/O than minor compactions.

**nodetool compactionhistory**

Provides the history of compaction operations.
Cassandra tools

Synopsis

$ nodetool <options> compactionhistory

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

Table 19: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could</td>
</tr>
<tr>
<td></td>
<td></td>
<td>be mistaken for a option.</td>
</tr>
</tbody>
</table>

Example

The actual output of compaction history is seven columns wide. The first three columns show the id, keyspace name, and table name of the compacted SSTable.

$ nodetool compactionhistory

<table>
<thead>
<tr>
<th>Compaction History:</th>
<th>id</th>
<th>keyspace_name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>d06f7080-07a5-11e4-9b36-abc3a0ec9088</td>
<td>system</td>
</tr>
<tr>
<td></td>
<td>d198ae40-07a5-11e4-9b36-abc3a0ec9088</td>
<td>libdata</td>
</tr>
<tr>
<td></td>
<td>0381bc30-07b0-11e4-9b36-abc3a0ec9088</td>
<td>Keyspace1</td>
</tr>
<tr>
<td></td>
<td>74eb69b0-0621-11e4-9b36-abc3a0ec9088</td>
<td>system</td>
</tr>
<tr>
<td></td>
<td>e35dd980-07ae-11e4-9b36-abc3a0ec9088</td>
<td>system</td>
</tr>
<tr>
<td></td>
<td>8d5cf160-07ae-11e4-9b36-abc3a0ec9088</td>
<td>system</td>
</tr>
<tr>
<td></td>
<td>ba376020-07af-11e4-9b36-abc3a0ec9088</td>
<td>Keyspace1</td>
</tr>
<tr>
<td></td>
<td>d18cc760-07a5-11e4-9b36-abc3a0ec9088</td>
<td>libdata</td>
</tr>
<tr>
<td></td>
<td>64009bf0-07a4-11e4-9b36-abc3a0ec9088</td>
<td>libdata</td>
</tr>
<tr>
<td></td>
<td>d04700f0-07a5-11e4-9b36-abc3a0ec9088</td>
<td>system</td>
</tr>
<tr>
<td></td>
<td>c2a97370-07a9-11e4-9b36-abc3a0ec9088</td>
<td>libdata</td>
</tr>
<tr>
<td></td>
<td>cb928a80-07ae-11e4-9b36-abc3a0ec9088</td>
<td>Keyspace1</td>
</tr>
</tbody>
</table>
The four columns to the right of the table name show the timestamp, size of the SSTable before and after compaction, and the number of partitions merged. The notation means \{tables:rows\}. For example: \{1:3, 3:1\} means 3 rows were taken from one SSTable (1:3) and 1 row taken from 3 SSTables (3:1) to make the one SSTable in that compaction operation.
nodetool compactionstats

Provide statistics about a compaction.

Synopsis

$ nodetool <options> compactionstats -H

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

Table 20: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
</tbody>
</table>
### Cassandra tools

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>-H</td>
<td>--human-readable</td>
<td>Display bytes in human readable form: KiB (kibibyte), MiB (mebibyte), GiB (gibibyte), TiB (tebibyte).</td>
</tr>
</tbody>
</table>

**Description**

The total column shows the total number of uncompressed bytes of SSTables being compacted. The system log lists the names of the SSTables compacted.

**Example**

```bash
$ nodetool compactionstats

pending tasks: 5

<table>
<thead>
<tr>
<th>compaction type</th>
<th>keyspace</th>
<th>table</th>
<th>completed</th>
</tr>
</thead>
<tbody>
<tr>
<td>total</td>
<td>unit progress</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Compaction</td>
<td>Keyspace1</td>
<td>Standard1</td>
<td>282310680</td>
</tr>
<tr>
<td>302170540</td>
<td>bytes 93.43%</td>
<td></td>
<td>307520780</td>
</tr>
<tr>
<td>Compaction</td>
<td>Keyspace1</td>
<td>Standard1</td>
<td>58457931</td>
</tr>
<tr>
<td>307520780</td>
<td>bytes 19.01%</td>
<td></td>
<td>307520780</td>
</tr>
</tbody>
</table>

Active compaction remaining time : 0h00m16s
```

### nodetool decommission

Deactivates a node by streaming its data to another node.

**Synopsis**

```bash
$ nodetool <options> decommission
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

**Table 21: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
</tbody>
</table>
Cassandra tools

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--</td>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Description
Causes a live node to decommission itself, streaming its data to the next node on the ring. Use netstats (page 300) to monitor the progress.

**nodetool describecluster**

Provide the name, snitch, partitioner and schema version of a cluster

Synopsis

```
$ nodetool <options> describecluster -- <datacenter>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

<table>
<thead>
<tr>
<th>Table 22: Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Short</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td>-h</td>
</tr>
<tr>
<td>-p</td>
</tr>
<tr>
<td>-pwf</td>
</tr>
<tr>
<td>-pw</td>
</tr>
<tr>
<td>-u</td>
</tr>
<tr>
<td>--</td>
</tr>
</tbody>
</table>

Description
Describe cluster is typically used to validate the schema after upgrading. If a schema disagreement occurs, check for and resolve schema disagreements (page 463).

Example

```
$ nodetool describecluster
```

Cluster Information:
Name: Test Cluster
Snitch: org.apache.cassandra.locator.DynamicEndpointSnitch
Partitioner: org.apache.cassandra.dht.Murmur3Partitioner
If a schema disagreement occurs, the last line of the output includes information about unreachable nodes.

```
$ nodetool describecluster
```

**nodetool describering**

Provides the partition ranges of a keyspace.

**Synopsis**

```
$ nodetool <options> describering -- <keyspace>
```

**DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

```
installation_location/resources/cassandra/bin
```

**Table 23: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td></td>
<td>keyspace</td>
<td>Name of keyspace.</td>
</tr>
<tr>
<td></td>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

**Example**

This example shows the sample output of the command on a three-node cluster.
$ nodetool describering demo_keyspace

Schema Version:1b04bd14-0324-3fc8-8bcb-9256d1e15f82
TokenRange:

<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td></td>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Description
This command effectively marks the node as being down.

**nodetool disablehandoff**

Disables storing of future hints on the current node.

**Synopsis**

```
$ nodetool <options> disablehandoff
```

**DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

`installation_location/resources/cassandra/bin`
### Table 28: Options

<table>

</tbody>
</table>

#### nodetool disablehintsfordc

Disable hints for a datacenter.

**Synopsis**

```
$ nodetool [options] disablehintsfordc [--] <datacenter>
```

**DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

```
installation_location/resources/cassandra/bin
```

**Note:**

- For tarball installations, execute the command from the `installation_location/bin` directory.
• If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.

• nodetool disablehintsfordc operates on a single node in the cluster if -h is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the -h option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using -h.

• [--] can be used to separate command-line options from the list of arguments, when the list might be mistaken for options.

Description

The nodetool disablehintsfordc command is used to turn off hints for a datacenter. This can be useful if there is a downed datacenter, but hints should continue on other datacenters. Another common case is during datacenter failover, when hints will put unnecessary pressure on the datacenter.

Examples

$ nodetool -u cassandra -pw cassandra disablehintsfordc DC2

The location of the cassandra-env.sh file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

nodetool disablethrift

Disables the Thrift server.

Synopsis

$ nodetool [options] disablethrift

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

Table 30: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
</tbody>
</table>
Cassandra tools

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Note:

- For tarball installations, execute the command from the install_location/bin directory.
- If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.
- nodetool disablethrift operates on a single node in the cluster if -h is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the -h option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using -h.

Description

nodetool disablethrift will disable thrift on a node preventing the node from acting as a coordinator. The node can still be a replica for a different coordinator and data read at consistency level ONE could be stale. To cause a node to ignore read requests from other coordinators, nodetool disablegossip would also need to be run. However, if both commands are run, the node will not perform repairs, and the node will continue to store stale data. If the goal is to repair the node, set the read operations to a consistency level of QUORUM or higher while you run repair. An alternative approach is to delete the node’s data and restart the Cassandra process.

Note that the nodetool commands using the -h option will not work remotely on a disabled node until nodetool enablethrift and nodetool enablegossip are run locally on the disabled node.

Examples

```
$ nodetool -u cassandra -pw cassandra disablethrift 192.168.100.1
```

nodetool drain

Drains the node.

Synopsis

```
$ nodetool <options> drain
```
DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

### Table 31: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>

<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

### Description

Flushes all memtables from the node to SSTables on disk. Cassandra stops listening for connections from the client and other nodes. You need to restart Cassandra after running `nodetool drain`. You typically use this command before upgrading a node to a new version of Cassandra. To simply flush memtables to disk, use `nodetool flush`.

**nodetool enableautocompaction**

Enables autocompaction for a keyspace and one or more tables.

### Synopsis

```
$ nodetool <options> enableautocompaction -- <keyspace> { <table> ... }
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

### Table 32: Options

</tr>
</tbody>
</table>

Description
The keyspace can be followed by one or more tables. Enables compaction for the named keyspace or the current keyspace, and one or more named tables, or all tables.

**nodetool enablebackup**

Enables incremental backup.

**Synopsis**

```
$ nodetool <options> enablebackup
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

**Table 33: Options**

<table>
<thead>
<tr>

<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
</tbody>
</table>

**datacenter**

The datacenter to enable.

**--**

Separates an option from an argument that could be mistaken for a option.

**Note:**

- For tarball installations, execute the command from the `install_location/bin` directory.
- If a username and password for RMI authentication are set explicitly in the `cassandra-env.sh` file for the host, then you must specify credentials.
- `nodetool enablehintsfordc` operates on a single node in the cluster if `-h` is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the `-h` option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using `-h`.
- `[--]` can be used to separate command-line options from the list of arguments, when the list might be mistaken for options.

**Description**

The `nodetool enablehintsfordc` command is used to turn on hints for a datacenter. The `cassandra.yaml` file has a parameter, `hinted_handoff_disabled_datacenters` *(page 109)* that will blacklist datacenters on startup. If a datacenter can be enabled later with `nodetool enablehintsfordc`.

**Examples**

```
$ nodetool -u cassandra -pw cassandra enablehintsfordc DC2
```

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>

</thead>
<tbody>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Description

You can specify a keyspace followed by one or more tables that you want to flush from the memtable to SSTables on disk.

**nodetool gcstats**

Print garbage collection (GC) statistics.

**Synopsis**

```
$ nodetool [options] gcstats
```

**DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

`installation_location/resources/cassandra/bin`

**Table 41: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

**Note:**

- For tarball installations, execute the command from the `install_location/bin` directory.
- If a username and password for RMI authentication are set explicitly in the `cassandra-env.sh` file for the host, then you must specify credentials.
- `nodetool gcstats` operates on a single node in the cluster if `-h` is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the `-h` option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using `-h`. 
Description

The `nodetool gcstats` command will print garbage collection statistics that returns values based on all the garbage collection that has run since the last time `nodetool gcstats` was run. Statistics identify the interval time, some GC elapsed time measures, the disk space reclaimed (in MB), number of garbage collections that took place, and direct memory bytes.

Examples

```
$ nodetool -u cassandra -pw cassandra gcstats
```

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>File Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td><code>/etc/dse/cassandra/cassandra-env.sh</code></td>

nodetool getcompactionthroughput

Print the throughput cap (in MB/s) for compaction in the system.

Synopsis

```
$ nodetool [options] getcompactionthroughput
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

Table 43: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>

<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Note:

- For tarball installations, execute the command from the `install_location/bin` directory.
- If a username and password for RMI authentication are set explicitly in the `cassandra-env.sh` file for the host, then you must specify credentials.
- `nodetool getcompactionthroughput` operates on a single node in the cluster if `-h` is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the `-h` option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using `-h`.

Description

The `nodetool getcompactionthroughput` command prints the current compaction throughput.
Examples

$ nodetool -u cassandra -pw cassandra getcompactionthroughput

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td>/etc/dse/cassandra/cassandra-env.sh</td>

<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/conf/cassandra-env.sh</code></td>
</tr>
</tbody>
</table>

**nodetool getendpoints**

Provides the IP addresses or names of replicas that own the partition key.

**Synopsis**

$ nodetool <options> getendpoints -- <keyspace> <table> key

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

**Table 44: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>

<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
</tbody>
</table>

`keyspace` Name of keyspace.

`table` Name of table.

`key` Partition key of the end points you want to get.

`--` Separates an option from an argument that could be mistaken for a option.
Cassandra tools

Example

For example, which nodes own partition key_1, key_2, and key_3?

Note: The partitioner returns a token for the key. Cassandra will return an endpoint whether or not data exists on the identified node for that token.

```bash
$ nodetool -h 127.0.0.1 -p 7100 getendpoints myks mytable key_1
127.0.0.2

$ nodetool -h 127.0.0.1 -p 7100 getendpoints myks mytable key_2
127.0.0.2

$ nodetool -h 127.0.0.1 -p 7100 getendpoints myks mytable key_2
127.0.0.1
```

**nodetool getinterdcstreamthroughput**

Prints the throughput cap in Megabits per second (Mbps) for inter-datacenter streaming.

**Synopsis**

```bash
$ nodetool options getinterdcstreamthroughput
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

*installation_location/resources/cassandra/bin*

**Table 45: Options**

<tbody>
<tr>
<td><code>-h</code></td>
<td><code>--host</code></td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td><code>-p</code></td>
<td><code>--port</code></td>
<td>Port number.</td>
</tr>
<tr>
<td><code>-pwf</code></td>
<td><code>--password-file</code></td>
<td>Password file path.</td>
</tr>
<tr>
<td><code>-pw</code></td>
<td><code>--password</code></td>
<td>Password.</td>
</tr>
<tr>
<td><code>-u</code></td>
<td><code>--username</code></td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td><code>keyspace</code></td>
<td></td>
<td>Name of keyspace.</td>
</tr>
<tr>
<td><code>table</code></td>
<td></td>
<td>One or more table names, separated by a space.</td>
</tr>
<tr>
<td><code>key</code></td>
<td></td>
<td>Partition key of the SSTables.</td>
</tr>
<tr>
<td><code>--</code></td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>
Description

This command can be used to retrieve an SSTable.

Examples

An example of this command retrieves the SSTable for `cycling.cyclist_name` with the key argument `fb372533-eb95-4bb4-8685-6ef61e994caa` for one of the cyclists listed:

```
$ nodetool getsstables cycling cyclist_name 'fb372533-eb95-4bb4-8685-6ef61e994caa'
```

The output is:

```
/homedir/datastax-ddc-3.6.0/data/data/cycling/cyclist_name-612a64002ec211e6a92457e568fce26f/ma-1-big-Data.db
```

```
$ nodetool getsstables keyspace1 standard1 3330394c344e35313730
```

**nodetool getstreamthroughput**

Provides the Mb (megabit) per second outbound throughput limit for streaming in the system.

Synopsis

```
$ nodetool <options> getstreamthroughput
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

| Table 49: Options |
|---|---|---|
| **Short** | **Long** | **Description** |
| -h | --host | Hostname or IP address. |
| -p | --port | Port number. |
| -pwf | --password-file | Password file path. |
| -pw | --password | Password. |
| -u | --username | Remote JMX agent username. |
nodetool gettimeout

Print the timeout value of the given type in milliseconds (Cassandra 3.4 and later).

Synopsis

$ nodetool [options] gettimeout [--] <timeout_type>

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

Table 50: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>

<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>timeout_type</td>
<td>The timeout type, one of read, range, write, counterwrite, cascontention, truncate, streamingsocket, misc (general rpc_timeout_in_ms).</td>
<td></td>
</tr>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

Note:

- For tarball installations, execute the command from the install_location/bin directory.
- If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.
- -- separates an option and argument that could be mistaken for a option.
- The timeout type:
  
  # read
  # range
  # write
  # counterwrite
Description

The `nodetool gettimeout` command prints the timeout value of the given type in milliseconds. Several timeouts are available.

Examples

```
$ nodetool -u cassandra -pw cassandra gettimeout read
```

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>File Location</th>

<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

**nodetool help**
Provides nodetool command help.

**Synopsis**

\$ nodetool help \(<command>\)

**DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

`installation_location/resources/cassandra/bin`
Description

The help command provides a synopsis and brief description of each nodetool command.

Examples

Using nodetool help lists all commands and usage information. For example, `nodetool help netstats` provides the following information.

| NAME | nodetool netstats – Print network information on provided host (connecting node by default) |
| SYNOPSIS | nodetool [(-h <host> | --host <host>)] [(-p <port> | --port <port>)] [(-pw <password> | --password <password>)] [(-u <username> | --username <username>)] netstats |
| OPTIONS | -h <host>, --host <host> Node hostname or ip address -p <port>, --port <port> Remote jmx agent port number -pw <password>, --password <password> Remote jmx agent password -u <username>, --username <username> Remote jmx agent username |

nodetool info

Provides node information, such as load and uptime.

Synopsis

$ nodetool <options> info -T | --tokens

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

Table 53: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
</tbody>
</table>
Cassandra tools

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>-T</td>
<td>--tokens</td>
<td>Show all tokens.</td>
</tr>
<tr>
<td></td>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Description

Provides node information including the token and on disk storage (load) information, times started (generation), uptime in seconds, and heap memory usage.

**nodetool invalidatecountercache**

Invalidates the counter cache, and resets the global counter cache parameter, counter_cache_keys_to_save, to the default (not set), which saves all keys..

**Synopsis**

```bash
$ nodetool [options] invalidatecountercache
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

**Table 54: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td></td>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

**Note:**

- For tarball installations, execute the command from the `install_location/bin` directory.
• If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.
• nodetool invalidatecountercache operates on a single node in the cluster if -h is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the -h option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using -h.

Description

The nodetool invalidatecountercache command will invalidate the counter cache, and the system will start saving all counter keys.

Examples

$ nodetool -u cassandra -pw cassandra invalidatecountercache

The location of the cassandra-env.sh file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>File Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

nodetool invalidatekeycache

Resets the global key cache parameter to the default, which saves all keys.

Synopsis

$ nodetool <options> invalidatekeycache

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

Table 55: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
</tbody>
</table>
### Description

By default the `key_cache_keys_to_save` is disabled in the `cassandra.yaml`. This command resets the parameter to the default.

The location of the `cassandra.yaml` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>

<td></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/resources/cassandra/</code></td>
</tr>
<tr>
<td></td>
<td><code>conf/cassandra.yaml</code></td>
</tr>
</tbody>
</table>

### nodetool invalidaterowcache

 Resets the global key cache parameter, `row_cache_keys_to_save`, to the default (not set), which saves all keys.

**Synopsis**

```bash
$ nodetool <options> invalidaterowcache
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

#### Table 56: Options

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

**nodetool join**

Causes the node to join the ring.

**Synopsis**

```
$ nodetool <options> join
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

**Table 57: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>

<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

**Description**

Causes the node to join the ring, assuming the node was initially not started in the ring using the `--join_ring=false` (page 367) cassandra utility option. The joining node should be properly configured with the desired options for seed list, initial token, and auto-bootstrapping.

**nodetool listendpointspendinghints**

Prints information about hints that the node has for other nodes.

Hint information includes Host ID, Address, Rack, DC (datacenter), node status, total number of hints and files, and timestamp of newest and oldest hints.
Cassandra tools

Synopsis

$ nodetool [connection_options] -h hostname listendpointspendinghints

Table 58: Legend

<table>
<thead>
<tr>
<th>Syntax conventions</th>

**nodetool mark_unrepaired**

Mark all SSTables of a table or keyspace as unrepaired. Use when no longer running incremental repair on a table or keyspace.

**WARNING:** This operation marks all targeted SSTables as unrepaired, potentially creating new compaction tasks. Only use if no longer running incremental repair on this node.

**Synopsis**

```
$ nodetool mark_unrepaired [-f] [--] keyspace_name [table_name ...]
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

**Nodetool general options**

The following options apply to all nodetool commands.
Table 61: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td>separators</td>
<td>Separates an option from an argument that could be mistaken for an option.</td>
</tr>
</tbody>
</table>

Options

- `-f`, `--force`
  Confirms the operation.

  **keyspace_name [table_name ...]**
  Requires a keyspace. To target specific tables, enter a space separated list of tables.

  **Note:** When no table name is specified, marks all tables in the keyspace as unrepaired.

nodetool move

Moves the node on the token ring to a new token.

Synopsis

```
$ nodetool <options> move -- <new token>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

Table 62: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>

<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

**Description**

Escape negative tokens using `\`. For example: `move \-123`. This command moves a node from one token value to another. This command is generally used to shift tokens slightly.

### nodetool netstats

Provides network information about the host.

**Synopsis**

```
$ nodetool <options> netstats -H
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

#### Table 63: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>

<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>_H</td>
<td>--human-readable</td>
<td>Display bytes in human readable form: KiB (kibibyte), MiB (mebibyte), GiB (gibibyte), TiB (tebibyte).</td>
</tr>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

**Description**

The default host is the connected host if the user does not include a host name or IP address in the command. The output includes the following information:
• JVM settings
• Mode

The operational mode of the node: JOINING, LEAVING, NORMAL, DECOMMISSIONED, CLIENT

• Read repair statistics
• Attempted

The number of successfully completed read repair operations (page 65)

• Mismatch (blocking)

The number of read repair operations since server restart that blocked a query.

• Mismatch (background)

The number of read repair operations since server restart performed in the background.

• Pool name

Information about client read and write requests by thread pool.

• Active, pending, and completed number of commands and responses

Example

Get the network information for a node 10.171.147.128:

$ nodetool -h 10.171.147.128 netstats

The output is:

<table>
<thead>
<tr>
<th>Pool Name</th>
<th>Active</th>
<th>Pending</th>
<th>Completed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Commands</td>
<td>n/a</td>
<td>0</td>
<td>1156</td>
</tr>
<tr>
<td>Responses</td>
<td>n/a</td>
<td>0</td>
<td>2750</td>
</tr>
</tbody>
</table>

nodetool pausehandoff

Pauses the hints delivery process

Synopsis

$ nodetool <options> pausehandoff
DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

### Table 64: Options

</tbody>
</table>
Description

The output of this command shows the full request latency recorded by the coordinator. The output includes the percentile rank of read and write latency values for inter-node communication. Typically, you use the command to see if requests encounter a slow node.

Examples

This example shows the output from nodetool proxyhistograms after running 4,500 insert statements and 45,000 select statements on a three ccm node-cluster on a local computer.

```
$ nodetool proxyhistograms
```

<table>
<thead>
<tr>
<th>Percentile</th>
<th>Read Latency (micros)</th>
<th>Write Latency (micros)</th>
<th>Range Latency (micros)</th>
</tr>
</thead>

Cassandra tools

---

Separates an option from an argument that could be mistaken for an option.

**nodetool rebuild**

Rebuilds data by streaming from other nodes.

**Synopsis**

```
$ nodetool options rebuild
[-dc | --dcs src_dc_names
[-mode | --mode rebuild_mode]
[ -ks | --keyspace keyspace_name [ , keyspace_name ] . . . ]
[ -ts | --tokens token_spec ]
[ -- source-dc-name ]
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

**Table 67: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dc</td>
<td>--dcs</td>
<td>The name of the datacenter that Cassandra uses as the source for streaming. Cassandra rebuilds from any datacenter. If a datacenter is not specified, Cassandra chooses at random.</td>
</tr>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-ks</td>
<td>--keyspace &lt;specific_keyspace&gt;</td>
<td>Rebuild specific keyspace.</td>
</tr>
<tr>
<td>-m</td>
<td>--mode</td>
<td>Rebuild mode.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>source-dc-name</td>
<td></td>
<td>Name of datacenter from which to select sources for streaming. By default, choose any datacenter.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for an option.</td>
</tr>
</tbody>
</table>
Parameters

-ks, --keyspace keyspace_name, ...
  (Cassandra 3.6 and later only) Comma-separated list of one or more keyspaces. List only the keyspaces to include in the rebuild.

  Tip: Do not include keyspaces that are not replicated across datacenters (for example, dsefs keyspaces, and keyspaces with local strategy).

rebuild_mode

- normal - conventional behavior. Streams only ranges that are not locally available. Default.
- refetch - resets locally available ranges. Streams all ranges but leaves current data untouched.
- reset - resets locally available ranges. Removes all locally present data (like a TRUNCATE). Streams all ranges.
- reset-no-snapshot - resets locally available ranges. Removes all locally present data (like a TRUNCATE). Streams all ranges. Prevents a snapshot if auto_snapshot (page 102) is enabled in cassandra.yaml.

token_spec (Cassandra 3.6 and later)

One or more tokens, and/or one or more ranges of tokens. The token_spec can be:

- One specific token.
- A comma-delimited list of single tokens.
- A range of tokens, specified as \((start_token, end_token)\).
- A comma-delimited list of token ranges — for example, \((start_token1, end_token1),(start_token2, end_token2),...\)
- A comma-delimited list of mixed single tokens and token ranges — for example, \(token1,(start_token2, end_token2),(start_token3, end_token3),token4,...\)

--

Separates an option and argument that could be mistaken for a option.

source-dc-name

The name of the datacenter Cassandra uses as the source for streaming. Cassandra rebuilds from any datacenter. If the statement does not specify one, Cassandra chooses at random.

Description

This command operates on multiple nodes in a cluster. Like nodetool bootstrap (page 254), rebuild only streams data from a single source replica when rebuilding a token range. Use this command to add a new datacenter (page 180) to an existing cluster.

If rebuild fails because some token ranges cannot be retrieved, you can rebuild selectively by using the -ts or --token option to specify a list of tokens, or one or more token ranges.
**Note:** If `rebuild` is interrupted before completion, you can restart it by re-entering the command. The process resumes from the point at which it was interrupted.

## nodetool rebuild_index

Performs a full rebuild of the index for a table

**Synopsis**

```bash
$ nodetool <options> rebuild_index -- <keyspace> <table> <indexName> ...
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

### Table 68: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>

**nodetool removenode**

Provides the status of current node removal, forces completion of pending removal, or removes the identified node.

**Warning:** This command triggers cluster streaming. In large environments, the additional streaming activity causes more pending gossip tasks in the output of nodetool tpstats. Nodes can start to appear offline and may need to be restarted to clear up the back log of pending gossip tasks.

Synopsis

$ nodetool <options> removenode -- <status> | <force> | <ID>

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

</tbody>
</table>

Description

This command removes a node, shows the status of a removal operation, or forces the completion of a pending removal. When the node is down and `nodetool decommission` cannot be used, use `nodetool removenode`. Run this command only on nodes that are down. If the cluster does not use vnodes, before running the `nodetool removenode` command, adjust the tokens (page 191).

Examples

Determine the UUID of the node to remove by running `nodetool status`. Use the UUID of the node that is down to remove the node.

```
$ nodetool status

Datacenter: DC1
============
Status=Up/Down
|/ State=Normal/Leaving/Joining/Moving

**nodetool repair**

The `repair` command repairs one or more nodes in a cluster, and provides options for restricting repair to a set of nodes, see [Repairing nodes](page 212). Performing an anti-entropy node repair on a regular basis is important, especially in an environment that deletes data frequently.

**Important:** Ensure that all involved replicas are up and accessible before running a repair. If repair encounters a down replica, an error occurs and the process halts. Re-run repair after bringing all replicas back online.

Control how the repair runs:

- **Number of nodes performing a repair:**
  - # Parallel runs repair on all nodes with the same replica data at the same time. (Default behavior in DataStax Enterprise 5.0 and later.)
  - # Sequential (`-seq`, `--sequential (page 314)`) runs repair on one node after another. (Default behavior in DataStax Enterprise 4.8 and earlier.)
  - # Datacenter parallel (`-dcpar`, `--dc-parallel (page 313)`) combines sequential and parallel by simultaneously running a sequential repair in all datacenters; a single node in each datacenter runs repair, one after another until the repair is complete.

- **Amount of data that is repaired:**
  - # Full repair (default) compares all replicas of the data stored on the node where the command runs and updates each replica to the newest version. Does not mark the data as repaired or unrepaired. Default for DataStax Enterprise 5.0.10 and higher. To switch to incremental repairs, see [Migrating to incremental repairs](page 222).
Cassandra tools

Full repair with partitioner range (-pr, --partitioner-range (page 314)) repairs only the primary replicas of the data stored on the node where the command runs. Recommended for routine maintenance.

Incremental repair (-inc (page 314)) splits the data into repaired and unrepaired SSTables, only repairs unrepaired data. Marks the data as repaired or unrepaired. Default behavior in DSE 5.0.0-5.0.9.

Note: Due to CASSANDRA-9143, DataStax recommends upgrading to DSE 5.0.10 (or later) and switching to full repairs, see Migrating to full repairs (page 221).

Notice: DSE changed the default behavior for nodetool repair as follows:

- **DSE 5.0.10 and later** runs full repair by default. To perform an incremental repair on a node running DSE 5.0.10 specify:

  ```
  $ nodetool repair -inc
  ```

- **DSE 5.0.0-5.0.9** runs incremental repair. To perform a full repair on a node running DSE 5.0.0-5.0.9 specify:

  ```
  $ nodetool repair -full
  ```

Synopsis

```
$ nodetool
   [(-h <host> | --host <host>) [(-p <port> | --port <port>)]
   [(-pw <password> | --password <password>)]
   [(-pwf <passwordFilePath> | --password-file <passwordFilePath>)]
   [(-u <username> | --username <username>)]
   repair
   [(-dc specific_dc | --in-dc specific_dc) ...]
   [(-dcpar | --dc-parallel)]
   [(-et end_token | --end-token end_token)]
   [(-full | --full)]
   [(-hosts specific_host | --in-hosts specific_host) ...]
   [-inc]
   [(-j job_threads | --job-threads job_threads)]
   [(-local | --in-local-dc)]
   [(-pr | --partitioner-range)]
   [(-pl | --pull)]
   [(-seq | --sequential)]
   [(-st start_token | --start-token start_token)]
   [(-tr | --trace)]
   [--]
   [keyspace [-] tables...]
```

Main options

The following options apply to all nodetool commands:
Table 74: Main options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Username.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates command parameters from a list of options.</td>
</tr>
</tbody>
</table>

Note:

- If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.

The location of the cassandra-env.sh file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>File Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/ cassandra/conf/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

- The repair and rebuild commands can affect multiple nodes in the cluster.
- Most nodetool commands operate on a single node in the cluster if -h is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the -h option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using -h.

Example:

```
$ nodetool -u username -pw password command command_options
```

Repair options

Repair specific options. See Manual repair: Anti-entropy repair (page 215) provides guidance on setting some of the following options.

- **-dc dc_name, --in-dc dc_name**
  Repair nodes in the named datacenter (dc_name). Datacenter names are case sensitive.
- **-dcp, --dc-parallel**
Cassandra tools

Runs a datacenter parallel repair, which combines sequential and parallel by simultaneously running a sequential repair in all datacenters; a single node in each datacenter runs repair, one after another until the repair is complete.

**-et end_token, --end-token end_token**
Token UUID. Repair a range of nodes starting with the first token (see `-st`) and ending with this token (`end_token`). Use `-hosts` to specify neighbor nodes.

**-full, --full**
Runs a full repair, which compares all replicas of the data stored on the node where the command runs and updates each replica to the newest version. Does not mark the data as repaired or unrepaired. Default for DataStax Enterprise 5.0.10 and higher. To switch to incremental repairs, see Migrating to incremental repairs (page 222).

**Note:** Option is only available on DSE 5.1.0-5.1.2, which by default runs incremental repairs. DataStax recommends upgrading to DSE 5.1.3 or later.

**-hosts specific_host, --in-hosts specific_host**
Repair specific hosts.

**-inc**
(Not recommended.) Runs an incremental repair, which persists already repaired data and calculates only the Merkle trees for SSTables that have not been repaired. Requires repairs to be run frequently (daily). Before running an incremental repair for the first time, perform migration steps (page 222) first. Never run an incremental repair to restore a node or after bringing a downed node back online.

**Note:** This parameter is only available in DSE 5.0.10 and later. DataStax recommends migrating to full repairs, see Changing repair strategies (page 221).

**-j job_threads, --job-threads job_threads**
Number of threads (`job_threads`) to run repair jobs. Usually the number of tables to repair concurrently. Be aware that increasing this setting puts more load on repairing nodes. (Default: 1, maximum: 4)

**-local, --in-local-dc**
Use to only repair nodes in the same datacenter.

**-pr, --partitioner-range**
Repair only the primary partition ranges of the node. To avoid re-repairing each range RF times, DataStax recommends using this option during routine maintenance (`nodetool repair -pr`) or using the OpsCenter Repair Service.

**Note:** Not recommend with incremental repair because incremental repairs marks data as repaired during each step and does not re-repair the same data multiple times.

**-pl, --pull**
Performs a one way repair where data is streamed from a remote node to this node.

**-seq, --sequential**
Runs a sequential repair, which runs repair on one node after another. (Default behavior in DataStax Enterprise 4.8 and earlier.)

**-st start_token, --start-token start_token**
Specify the token (`start_token`) at which the repair range starts.
-tr, --trace
    Trace the repair. Traces are logged to system_traces.events.

keyspace_name table_list
    Name of keyspace and space separated list of tables.

--
    Separates an option from an argument that could be mistaken for a option.

Example

All nodetool repair arguments are optional.

To do a sequential repair of all keyspaces on the current node:

$ nodetool repair -seq

To do a partitioner range repair of the bad partition on current node using the good partitions on 10.2.2.20 or 10.2.2.21:

$ nodetool repair -pr -hosts 10.2.2.20 10.2.2.21

For a start-point-to-end-point repair of all nodes between two nodes on the ring:

$ nodetool repair -st -92237036854775808 -et -3074457345618258603

To restrict the repair to the local datacenter, use the -dc option followed by the name of the datacenter. Issue the command from a node in the datacenter you want to repair. Issuing the command from a datacenter other than the named one returns an error. Do not use -pr with this option to repair only a local data center.

$ nodetool repair -dc DC1

Results in output:

    for keyspace system_traces (seq=true, full=true)
    for range (820981369067266915,822627736366088177] finished
    for range (2506042417712465541,251594126269962473] finished
    ...

And an inspection of the system.log shows repair taking place only on IP addresses in DC1.

    ...
    RepairSession.java:171
    - [repair #16499ef0-1381-11e4-88e3-c972e09793ca] Received merkle tree
    for sessions from /192.168.2.101
nodetool replaybatchlog

Replay batchlog and wait for finish.

Synopsis

$ nodetool <options> replaybatchlog

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

Table 75: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>

<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Description

nodetool replaybatchlog is intended to force a batchlog replay. It also blocks until the batches have been replayed.

nodetool resetlocalschema

Reset the node’s local schema and resynchronizes.

Synopsis

$ nodetool [options] resetlocalschema [args]

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin
Table 76: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>

<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

Note:

- For tarball installations, execute the command from the `install_location/bin` directory.
- If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.
- `nodetool resetlocalschema` operates on a single node in the cluster if `-h` is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the `-h` option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using `-h`.

Description

Normally, this command is used to rectify schema disagreements on different nodes. It can be useful if table schema changes have generated too many tombstones, on the order of 100,000s.

`nodetool resetlocalschema` drops the schema information of the local node and resynchronizes the schema from another node. To drop the schema, the tool truncates all the `system` schema tables. The node will temporarily lose metadata about the tables on the node, but will rewrite the information from another node. If the node is experiencing problems with too many tombstones, the truncation of the tables will eliminate the tombstones.

This command is useful when you have one node that is out of sync with the cluster. The `system` schema tables must have another node from which to fetch the tables. It is not useful when all or many of your nodes are in an incorrect state. If there is only one node in the cluster (replication factor of 1) – it does not perform the operation, because another node
from which to fetch the tables does not exist. Run the command on the node experiencing difficulty.

**nodetool resumehandoff**

Resume hints delivery process.

**Synopsis**

`$ nodetool <options> resumehandoff`

<table>
<thead>
<tr>
<th>Table 77: Options</th>
</tr>
</thead>
<tbody>

<tr>
<td>-pw</td>
</tr>
<tr>
<td>-u</td>
</tr>
<tr>
<td>-r</td>
</tr>
<tr>
<td>keyspace</td>
</tr>
<tr>
<td>--</td>
</tr>
</tbody>
</table>

### Description

Displays node status and information about the ring as determined by the node being queried. This information can give you an idea of the load balance and if any nodes are down. If your cluster is not properly configured, different nodes may show a different ring. Check that the node appears the same way in the ring. If you use virtual nodes (vnodes), use `nodetool status` for succinct output.

- **Address**
  - The node's URL.

- **DC (datacenter)**
  - The datacenter containing the node.

- **Rack**
  - The rack or, in the case of Amazon EC2, the availability zone of the node.

- **Status - Up or Down**
  - Indicates whether the node is functioning or not.

- **State - N (normal), L (leaving), J (joining), M (moving)**
  - The state of the node in relation to the cluster.

- **Load - updates every 90 seconds**
  - The amount of file system data under the cassandra data directory after excluding all content in the snapshots subdirectories. Because all SSTable data files are included, any data that is not cleaned up, such as TTL-expired cell or tombstoned data) is counted.

- **Token**
The end of the token range up to and including the value listed. For an explanation of token ranges, see Data Distribution in the Ring (page 383).

- **Owns**
  The percentage of the data owned by the node per datacenter times the replication factor. For example, a node can own 33% of the ring, but show 100% if the replication factor is 3.

- **Host ID**
  The network ID of the node.

### nodetool scrub

Creates a snapshot and then rebuilds SSTables on a node. If possible use nodetool upgradesstables (page 364) instead of scrub.

Scrub automatically discards broken data and removes any tombstoned rows that have exceeded gc_grace period of the table. If partition key values do not match the column data type, the partition is considered corrupt and the process automatically stops.

**Attention:** When using LCS, resets all SSTables back to Level 0 and requires recompaction of all SSTables.

### Synopsis

```
nodetool main_options scrub [(-j <jobs> | --jobs <jobs>)]
[(-n | --no-validate)][(-ns | --no-snapshot)]
[(-s | --skip-corrupted)]
[--] [<keyspace> <tables>...]
```

### Main options

The following options apply to all nodetool commands:

**Table 79: Main options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Username.</td>
</tr>
</tbody>
</table>
Cassandra tools

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--</td>
<td></td>
<td>Separates command parameters from a list of options.</td>
</tr>
</tbody>
</table>

**Note:**

- If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.

The location of the cassandra-env.sh file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

- The repair and rebuild commands can affect multiple nodes in the cluster.
- Most nodetool commands operate on a single node in the cluster if -h is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the -h option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using -h.

Example:

```
$ nodetool -u username -pw password command command_options
```

**Scrub parameters**

Use the following parameters with the scrub command:

- **-j | --jobs jobs**
  Number of SSTables to simultaneously scrub. Zero (0) uses all available compaction threads.
  
  Default: 2.

- **-n | --no-validate**
  Suppresses validation of columns.
  
  Default: Validate all columns.

- **-ns | --no-snapshot**
  Suppresses creation of snapshot.
  
  Default: Create a snapshot before rebuilding SSTables.

- **--reinsert-overflowed-ttl**
Rewrite SSTables containing rows with overflowed expiration time with the maximum expiration date of 2038-01-19T03:14:06+00:00 using the original timestamp + 1 (ms).

-s | --skip-corrupted
Forces scrub to skip corrupt partitions and continue. Corrupt partitions have a column value that does not match the column data type. Logs skipped partitions in the system.log.

Default: Stop scrubbing if a corrupted partition is detected.

Note: Skipping corrupted partitions on tables with counter columns results in under-counting.

keyspace_name table_name [...]  
Identifies the keyspace and targets specific tables using a space separated list.

Default: Include all keyspaces and tables on the node when no arguments are specified.

**nodetool setcachecapacity**

Set global key and row cache capacities in megabytes.

**Synopsis**

```
$ nodetool <options> setcachecapacity -- <key-cache-capacity> <row-cache-capacity>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

**Table 80: Options**

<table>
<thead>
<tr>

<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
</tbody>
</table>
| key-cache
          | capacity          | Maximum size in MB of the key cache in memory. |
| row-cache
          | capacity          | Maximum size in MB of the row cache in memory. |
### Description

The key-cache-capacity argument corresponds to the `key_cache_size_in_mb` (page 102) parameter in the `cassandra.yaml`. Each key cache hit saves one seek and each row cache hit saves a minimum of two seeks. Devoting some memory to the key cache is usually a good tradeoff considering the positive effect on the response time. The default value is empty, which means a minimum of five percent of the heap in MB or 100 MB.

The row-cache-capacity argument corresponds to the `row_cache_size_in_mb` (page 103) parameter in the `cassandra.yaml`. By default, row caching is zero (disabled).

The counter-cache-capacity argument corresponds to the `counter_cache_size_in_mb` (page 103) in the `cassandra.yaml`. By default, counter caching is a minimum of 2.5% of Heap or 50MB.

The location of the `cassandra.yaml` (page 102) file depends on the type of installation:

| DataStax Enterprise 5.0 Installer-Services and package installations | /etc/dse/cassandra/cassandra.yaml |
| DataStax Enterprise 5.0 Installer-No Services and tarball installations | `install_location/resources/cassandra/conf/cassandra.yaml` |
| Cassandra package installations | /etc/cassandra/cassandra.yaml |
| Cassandra tarball installations | `install_location/resources/cassandra/conf/cassandra.yaml` |

#### nodetool setcachekeystosave

Sets the number of keys saved by each cache for faster post-restart warmup.

**Synopsis**

```
$ nodetool <options> setcachekeystosave -- <key-cache-keys-to-save> <row-cache-keys-to-save>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

`installation_location/resources/cassandra/bin`

### Table 81: Options

</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

### Description

This command saves the specified number of key and row caches to the saved caches directory, which you specify in the cassandra.yaml. The key-cache-keys-to-save argument corresponds to the key_cache_keys_to_save in the cassandra.yaml, which is disabled by default, meaning all keys will be saved. The row-cache-keys-to-save argument corresponds to the row_cache_keys_to_save in the cassandra.yaml, which is disabled by default.

The location of the cassandra.yaml (page 324) file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/cassandra.yaml</td>

<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

### nodetool setcompactionthreshold

Sets minimum and maximum compaction thresholds for a table.
Synopsis

$ nodetool <options> setcompactionthreshold -- <keyspace> <table> 
<minthreshold> <maxthreshold>

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

Table 82: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>

</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>keyspace</td>
<td></td>
<td>Name of a keyspace.</td>
</tr>
<tr>
<td>table</td>
<td></td>
<td>Name of a table.</td>
</tr>
<tr>
<td>minthreshold</td>
<td></td>
<td>Sets the minimum number of SSTables to trigger a minor compaction when using SizeTieredCompactionStrategy or DateTieredCompactionStrategy.</td>
</tr>
<tr>
<td>maxthreshold</td>
<td></td>
<td>Sets the maximum number of SSTables to allow in a minor compaction when using SizeTieredCompactionStrategy or DateTieredCompactionStrategy.</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Description

This parameter controls how many SSTables of a similar size must be present before a minor compaction (page 41) is scheduled. The max_threshold (page 43) table property sets an upper bound on the number of SSTables that may be compacted in a single minor compaction.
When using LeveledCompactionStrategy, maxthreshold sets the MAX_COMPACTING_L0, which limits the number of L0 SSTables that are compacted concurrently to avoid wasting memory or running out of memory when compacting highly overlapping SSTables.

**nodetool setcompactionthroughput**

Sets the throughput capacity for compaction in the system, or disables throttling.

**Synopsis**

```
$ nodetool <options> setcompactionthroughput -- <value_in_mb>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

**Table 83: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>value_in_mb</td>
<td>The throughput capacity in MB per second for compaction. To disable throttling, set to 0.</td>
<td></td>
</tr>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

**Description**

Set `value_in_mb` to 0 to disable throttling.

**nodetool sethintedhandoffthrottlekb**

Sets hinted handoff throttle in kb/sec per delivery thread.

**Synopsis**

```
$ nodetool <options> sethintedhandoffthrottlekb <value_in_kb/sec>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:
Table 84: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>value_in_kb/sec</td>
<td>Throttle time in kilobytes per second.</td>
<td></td>
</tr>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

Description

When a node detects that a node for which it is holding hints has recovered, it begins sending the hints to that node. This setting specifies the maximum sleep interval per delivery thread in kilobytes per second after delivering each hint. The interval shrinks proportionally to the number of nodes in the cluster. For example, if there are two nodes in the cluster, each delivery thread uses the maximum interval; if there are three nodes, each node throttles to half of the maximum interval, because the two nodes are expected to deliver hints simultaneously.

Example

$ nodetool sethintedhandoffthrottlekb 2048

**nodetool setinterdcstreamthroughput**

Sets the inter-datacenter throughput capacity in megabits per second (Mbps) streaming, or 0 to disable throttling.

**Synopsis**

```
   nodetool options setinterdcstreamthroughput [--] value_in_mbps
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:
Table 85: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>value_in_mbps</td>
<td>Throughput capacity in megabits per second for streaming. To disable, set to 0.</td>
<td></td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Description
Set to 0 to disable throttling.

**nodetool setlogginglevel**

Set the log level for a service.

**Synopsis**

```
$ nodetool <options> setlogginglevel -- <class> <level>
```

Table 86: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>class</td>
<td></td>
<td>The class for changing the level, a fully qualified domain name such as org.apache.cassandra.service.StorageProxy.</td>
</tr>
<tr>
<td>level</td>
<td></td>
<td>Logging level, for example DEBUG.</td>
</tr>
<tr>
<td>Short</td>
<td>Long</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

**Description**

You can use this command to set logging levels for services instead of modifying the logback-text.xml file. The following values are valid for the logger class qualifier:

- `org.apache.cassandra`
- `org.apache.cassandra.db`
- `org.apache.cassandra.service.StorageProxy`

The possible log levels are:

- `ALL`
- `TRACE`
- `DEBUG`
- `INFO`
- `WARN`
- `ERROR`
- `OFF`

If both class qualifier and level arguments to the command are empty or null, the command resets logging to the initial configuration.

**Example**

This command sets the StorageProxy service to debug level.

```
$ nodetool setlogginglevel org.apache.cassandra.service.StorageProxy DEBUG
```

**Note:** Cassandra 3.0 and later support extended logging for Compaction. This utility must be configured as part of the table configuration. The extended compaction logs are stored in a separate file. For details, see [Enabling extended compaction logging](page).  

**nodetool setstreamthroughput**

Sets the throughput capacity in Mb (megabits) for streaming in the system, or disables throttling.

**Synopsis**

```
$ nodetool <options> setstreamthroughput -- <value_in_mb>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:
Cassandra tools

`installation_location/resources/cassandra/bin`

**Table 87: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>value_in_mb</td>
<td></td>
<td>Throughput capacity in megabits per second for streaming. To disable, set to 0.</td>
</tr>
</tbody>
</table>

**Description**
Set value_in_mb to 0 to disable throttling.

**nodetool settimeout**

Set the specified timeout in milliseconds, or 0 to disable timeout. (Cassandra 3.4 and later).

**Synopsis**

```
$ nodetool [options] settimeout [--] <timeout_type> <timeout_in_ms>
```

**DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

`installation_location/resources/cassandra/bin`

**Table 88: Options**

<table>

<td>timeout_in_ms). Type should be one of read, range, write, counterwrite, cascontention, truncate, streamingsocket, misc (general</td>
</tr>
<tr>
<td></td>
<td></td>
<td>timeout_in_ms). Type should be one of read, range, write, counterwrite, cascontention, truncate, streamingsocket, misc (general</td>
</tr>
<tr>
<td></td>
<td></td>
<td>timeout_in_ms). Type should be one of read, range, write, counterwrite, cascontention, truncate, streamingsocket, misc (general</td>
</tr>
</tbody>
</table>

**Note:**

- For tarball installations, execute the command from the `install_location/bin` directory.
- If a username and password for RMI authentication are set explicitly in the `cassandra-env.sh` file for the host, then you must specify credentials.
- **--** separates an option and argument that could be mistaken for a option.
- The timeout type:
  
  # read
  
  # range
  
  # write
  
  # counterwrite
  
  # cascontention
  
  # truncate
  
  # streamingsocket
  
  # misc, such as general rpc_timeout_in_ms

**Description**

The nodetool gettimeout command sets the specified timeout in milliseconds. Use "0" to disable a timeout. Several timeouts are available.

**Examples**

```
$ nodetool -u cassandra -pw cassandra settimeout read 100
```

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>
<th>/etc/dse/cassandra/cassandra-env.sh</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
</tbody>
</table>
nodetool settraceprobability

Sets the probability for tracing a request.

Synopsis

```
$ nodetool <options> settraceprobability -- <value>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

Table 89: Options

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>

<tr>
<td>value</td>
<td>Trace probability</td>
<td>Trace probability between 0 and 1. For example: 0.2.</td>
</tr>
<tr>
<td></td>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Description

Probabilistic tracing is useful to determine the cause of intermittent query performance problems by identifying which queries are responsible. This option traces some or all statements sent to a cluster. Tracing a request usually requires at least 10 rows to be inserted.

A probability of 1.0 will trace everything whereas lesser amounts (for example, 0.10) only sample a certain percentage of statements. Care should be taken on large and active systems, as system-wide tracing will have a performance impact. Unless you are under very light load, tracing all requests (probability 1.0) will probably overwhelm your system. Start with a small fraction, for example, 0.001 and increase only if necessary. The trace information is stored in a system_traces keyspace that holds two tables – sessions and events, which can be easily queried to answer questions, such as what the most time-consuming query has been since a trace was started. Query the parameters map and thread column in the system_traces.sessions and events tables for probabilistic tracing information.
To discover the current trace probability setting, use `nodetool gettraceprobability` (page 289).

**nodetool sjk**

Runs Swiss Java Knife (SJK) commands to execute, troubleshoot, and monitor the database using MBeans.

**Synopsis**

```
nodetool sjk options command command_options
```

**DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

```
installation_location/resources/cassandra/bin
```

**Nodetool general options**

The following options apply to all nodetool commands.

**Table 90: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

**Options**

**General Swiss Java Knife options.**

--commands

Displays a list of all SJK commands.

--help

Displays command specific help, for example `nodetool sjk ttop --help`.

-X, --verbose

Displays detailed diagnostics.

**Commands**

DataStax supports running SJK commands from nodetool.
Cassandra tools

mxdump
Prints serialized MBeans to JSON format.

Warning:

The nodetool s jk mxdump command tries to print all exposed MBeans to the console. The command can fail if it encounters an improperly formatted MBean that exposes a non-serializable type. To interact with a specific list of MBeans, use the nodetool s jk mx command.

Run the nodetool s jk mx command with the -q (query) switch to avoid errors if a non-serializable type (such as an mx4j MBean) is returned.

-q, --query
Output selected MBeans by specifying the ObjectName; match patterns using the asterisk (*) and question mark (?) wildcards.

For example, to get all values for Garbage Collector:

```
nodetool s jk mxdump -q
java.lang:type=GarbageCollector,name=*
```

gc
Print GC (garbage collection) log messages for remote process.

For example, to print the GC log messages:

```
nodetool s jk gc
```

Note: No options for GC.

hh
Heap histogram (hh) prints the class histogram, similar to jmap -histo. When no options are specified, prints complete histogram for all objects.

Note: For package installations, run nodetool with the account the runs the database.

For example, to print a histogram for young with a sample duration of 10000 milliseconds on a system with DSE package installation:

```
sudo -u cassandra nodetool s jk hh --young --sample-depth 10000ms -n 10
```

-d, --sample-depth
Specify an integer and unit to set the sample duration for --dead-young (page 335) or --young (page 335); default: 10000ms. To set the unit, use the following notation:
Cassandra tools

- **ms** (milliseconds)
- **s** (seconds)
- **m** (minutes)
- **h** (hours)
- **d** (days)

---dead

Prints histogram of dead objects.

---dead-young

Prints histogram for sample of dead young objects. Use with `-d (page 334)` to set the duration.

---live

Prints histogram of live objects.

- **-n, --top-number**
  Limits the number of buckets for $N$ top buckets; default: 2147483647.

---young

Prints histogram for a sample of the new objects. Use with `-d (page 334)` to set the duration.

mx

Provides query and execution for Mbeans from the nodetool interface.

- **-all, --allMatched**
  Process all matched MBeans.

- **-a, --arguments**
  Arguments for MBean operation invocation.

- **-f, --field, --attribute**
  MBean attribute

- **-b, --bean**
  Mbean name.

- **-mc, --call**
  Invokes MBean method. Default false.

- **-mg, --get**
  Retrieves value of MBean attribute. Default false.

- **-mi, --info**
  Display metadata for MBean. Default false.

- **--max-col-width**
  Table column width threshold for formatting tabular data. Default 40.

- **-op, --operation**
  MBean operation name to be called.

- **--quiet**
  Avoid non-essential output; default: false.

- **-ms, --set**
  Sets value for MBean attribute; default: false.

- **-v, --value**
  Value to set for MBean attribute.
jps
Enhanced version of `jps` tool from the Java Development Kit (JDK) that lists the instrumented HotSpot Java Virtual Machines (JVMs) on the target system.

- **-fd, --filter-description**
  Use a wildcard expression to match the process description.

- **-fp, --filter-property**
  Use a wildcard expressions to match JVM system properties.

- **-pd, --process-details**
  Prints custom information related to a process; set to PID, MAIN, FDQN_MAIN, ARGS, Dsys-prop, or Dsys-prop.

- **Xjvm-flag**
  Prints custom information related to the specified JVM flag.

stcap
Stack Capture dumps stack traces to file for further processing.

- **-e, --empty**
  Set to true to retain threads without stack trace in dump (ignored by default); default: false.

- **-f, --filter**
  Filters threads by name using Java RegEx syntax; default: .*  
  **Note:** The default value, period (.) followed by asterisk (*), allows any number of any characters, including nulls.

- **-l, --limit**
  Target number of traces to collect, once reached command terminates where 0 is unlimited; default: 0.

- **-m, --match-frame**
  Set to filtering string and only traces containing are included in the dump.

- **-o, --output**
  Write the thread dump to the specified a file name.

- **-r, --rotate**
  When specified output file would be rotated every N traces. Specify 0 for no rotation; default: 0.

- **-i, --sampler-interval**
  Interval between polling MBeans; default: 0.

- **-t, --timeout**
  Time until command terminate even without enough traces collected; default: 30000.

stcpy
Stack Copy utility copies and filters dumps.

- **-e, --empty**
Set to true to retain threads without stack trace in dump (ignored by default); default: false.

-\texttt{--input} \hspace{1cm} \textbf{Input files.}

-\texttt{--mask} \hspace{1cm} \textbf{One or more masking rules, for example }\texttt{com.mycompany:com.somecompany}; default: \texttt{null}.

-\texttt{--match-frame} \hspace{1cm} \textbf{Frame filter, only traces containing the string are included in dump.}

-\texttt{--output} \hspace{1cm} \textbf{Set to filename. Writes thread dump to the specified file.}

-\texttt{--subsample} \hspace{1cm} \textbf{If below 1.0 some frames are randomly thrown away. For example, 0.1 retains only every 10th frame; default: 1.0.}

-\texttt{--thread-filter} \hspace{1cm} \textbf{Filter threads by name using Java RegEx syntax; default: .*}

\texttt{ssa}

\textbf{Stack Sample Analyzer for stack trace dumps.}

-\texttt{--categorize} \hspace{1cm} \textbf{Prints summary for provided categorization; no summary printed by default.}

-\texttt{--categorizer-file} \hspace{1cm} \textbf{Path to file with stack trace categorization definition.}

-\texttt{--csv-output} \hspace{1cm} \textbf{Output data in CSV format; default: false.}

-\texttt{--file} \hspace{1cm} \textbf{Path to stack dump file.}

-\texttt{--flame} \hspace{1cm} \textbf{Exports flame graph to SVG format; default: not included.}

-\texttt{--histo} \hspace{1cm} \textbf{Prints frame histogram; default: not included.}

-\texttt{--named-class} \hspace{1cm} \textbf{Defines name stack trace. Use with other options.}

-\texttt{classes} \hspace{1cm} \textit{Use }name=filter expression\textit{ notation; default: no expression.}

-\texttt{--print} \hspace{1cm} \textbf{Print traces from file; default: not included.}

-\texttt{--rainbow} \hspace{1cm} \textbf{List of filters for rainbow coloring.}

-\texttt{--ssa-help} \hspace{1cm} \textbf{Provides additional information about SSA options; default: not shown.}

-\texttt{--summary-info} \hspace{1cm} \textbf{Lists summaries.}

-\texttt{--thread-info} \hspace{1cm} \textbf{Prints per thread information summary; default: false.}

-\texttt{--thread-name} \hspace{1cm} \textbf{Filters thread name using Java RegEx syntax.}
Cassandra tools

--tr, --time-range
Filters time range.

--tz, --time-zone
Time zone used for timestamps; default: UTC. Use --ssa-help for timezone notation.

--title
Inserts a flame graph title; default: Flame Graph.

tf, --trace-filter
Applies filter to traces before processing. Use --ssa-help for more details about filter notation.

--width
Flame graph width in pixels; default: 1200.

ttop
Displays top threads from JVM process.

-f, --filter
Wild card expression to filter threads by name.

-o, --order
Sort order. Value tags: CPU, USER, SYS, ALLOC, NAME; default: CPU.

ri, --report-interval
Interval between CPU usage reports; default: 10000.

si, --sampler-interval
Interval between polling MBeans; default: 500.

-n, --top-number
Number of threads to show; default: 20.

nodetool snapshot

Take a snapshot of one or more keyspaces, or of a table, to backup data.

Synopsis

```bash
$ nodetool <options> snapshot
    ( -cf <table> | --column-family <table> )
    ( -kc <ktlist> | --kc.list <ktlist> | -kt <ktlist> | --kt-list <ktlist>
    ( -sf | --skip-flush)
    ( -t <tag> | --tag <tag> )
    -- ( <keyspace> | <keyspace> ... )
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```
### Table 91: Options

<tr>
<td>keyspace</td>
<td>One or more optional keyspace names, separated by a space. Default: all keyspaces</td>
<td></td>
</tr>
<tr>
<td>--</td>
<td></td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

**Description**

Use this command to back up data (page 202) using a snapshot. See the examples below for various options.

Cassandra flushes (page 39) the node before taking a snapshot, takes the snapshot, and stores the data in the snapshots directory (page 85) of each keyspace in the data directory. If you do not specify the name of a snapshot directory using the -t option, Cassandra names the directory using the timestamp of the snapshot, for example 1391460334889. Follow the procedure for taking a snapshot (page 203) before upgrading Cassandra. When upgrading, backup all keyspaces.
Cassandra tools

Example: All keyspaces

Take a snapshot of all keyspaces on the node. On Linux, in the Cassandra bin directory, for example:

$ nodetool snapshot

The following message appears:

Requested creating snapshot(s) for [all keyspaces] with snapshot name [1391464041163]
Snapshot directory: 1391464041163

Because you did not specify a snapshot name, Cassandra names snapshot directories using the timestamp of the snapshot.

Example: Single keyspace snapshot

Assuming you created the keyspace cycling, took a snapshot of the keyspace and named the snapshot 2015.07.17:

$ nodetool snapshot -t 2015.07.17 cycling

The following output appears:

Requested creating snapshot(s) for [cycling] with snapshot name [2015.07.17]
Snapshot directory: 2015.07.17

Assuming the cycling keyspace contains two tables, cyclist_name and upcoming_calendar, taking a snapshot of the keyspace creates multiple snapshot directories named 2015.07.17. A number of .db files containing the data are located in these directories. For example, from the installation directory:

$ cd data/data/cycling/cyclist_name-a882dca02aaf11e58c7b8b496c707234/snapshots/2015.07.17
$ ls

la-1-big-CompressionInfo.db  la-1-big-Index.db  la-1-big-TOC.txt
la-1-big-Data.db     la-1-big-Statistics.db  la-1-big-
Digest.adler32       la-1-big-Summary.db  manifest.json

$ cd data/data/cycling/cyclist_name-a882dca02aaf11e58c7b8b496c707234/snapshots/2015.07.17
$ ls

la-1-big-CompressionInfo.db  la-1-big-Index.db  la-1-big-TOC.txt
la-1-big-Data.db     la-1-big-Statistics.db  la-1-big-
Digest.adler32       la-1-big-Summary.db  manifest.json
Example: Multiple keyspaces snapshot

Assuming you created a keyspace named `mykeyspace` in addition to the `cycling` keyspace, take a snapshot of both keyspaces.

```
$ nodetool snapshot mykeyspace cycling
```

The following message appears:

```
Requested creating snapshot(s) for [mykeyspace, cycling] with snapshot name [1391460334889]
Snapshot directory: 1391460334889
```

Example: Single table snapshot

Take a snapshot of only the `cyclist_name` table in the `cycling` keyspace.

```
$ nodetool snapshot --table cyclist_name cycling
```

Requested creating snapshot(s) for [cycling] with snapshot name [1391461910600]
Snapshot directory: 1391461910600

Cassandra creates the snapshot directory named 1391461910600 that contains the backup data of `cyclist_name` table in `data/data/cycling/cyclist_name-a882dca02aaf11e58c7b8b496c707234/snapshots`, for example.

Example: List of different keyspace.tables snapshot

Take a snapshot of several tables in different keyspaces, such as the `cyclist_name` table in the `cycling` keyspace and the `sample_times` table in the `test` keyspace. The `keyspace.table` list should be comma-delimited with no spaces.

```
$ nodetool snapshot -kt cycling.cyclist_name,test.sample_times
```

Requested creating snapshot(s) for [cycling.cyclist_name,test.sample_times] with snapshot name [1431045288401]
Snapshot directory: 1431045288401

### nodetool status

Provide information about the cluster, such as the state, load, and IDs.

**Synopsis**

```
$ nodetool <options> status ( -r | --resolve-ip ) -- <keyspace>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:
Table 92: Options

<table>
<thead>
<tr>
<th>Short</th>

<tr>
<td>-r</td>
<td>--resolve-ip</td>
<td>Show node names instead of IP addresses.</td>
</tr>
</tbody>
</table>

```
keystore
```

Name of keyspace.

```
--
```
Separates an option from an argument that could be mistaken for a option.

Description

The status command provides the following information:

- Status - U (up) or D (down)

  Indicates whether the node is functioning or not.

- State - N (normal), L (leaving), J (joining), M (moving)

  The state of the node in relation to the cluster.

- Address

  The node's URL.

- Load - updates every 90 seconds

  The amount of file system data under the cassandra data directory after excluding all content in the snapshots subdirectories. Because all SSTable data files are included, any data that is not cleaned up, such as TTL-expired cell or tombstoned data) is counted.

- Tokens

  The number of tokens set for the node.

- Owns
Cassandra tools

The percentage of the data owned by the node per datacenter times the replication factor. For example, a node can own 33% of the ring, but show 100% if the replication factor is 3.

**Attention:** If your cluster uses keyspaces having different replication strategies or replication factors, specify a keyspace when you run `nodetool status` to get meaningful ownership information.

- **Host ID**
  
The network ID of the node.

- **Rack**
  
The rack or, in the case of Amazon EC2, the availability zone of the node.

**Example**

This example shows the output from running `nodetool status`.

```
$ nodetool status mykeyspace

Datacenter: datacenter1

Status=Up/Down
|/ State=Normal/Leaving/Joining/Moving
-- Address    Load       Tokens  Owns    Host ID  Rack
 UN 127.0.0.1  47.66 KB   1       33.3%   aaa1b7c1-6049-4a08-ad3e-3697a0e30e10  rack1
 UN 127.0.0.2  47.67 KB   1       33.3%   1848c369-4306-4874-afdf-5c1e95b8732e  rack1
 UN 127.0.0.3  47.67 KB   1       33.3%   49578bf1-728f-438d-b1c1-d8dd644b6f7f  rack1
```

**nodetool statusbackup**

**Synopsis**

```
$ nodetool <options> statusbackup
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
</tbody>
</table>

**compaction type**

Supported types are COMPACTION, VALIDATION, CLEANUP, SCRUB, VERIFY, INDEX_BUILD.

--

Separates an option from an argument that could be mistaken for a option.

**Note:**

- For tarball installations, execute the command from the install_location/bin directory.
- If a username and password for RMI authentication are set explicitly in the cassandra-env.sh file for the host, then you must specify credentials.
- nodetool stop operates on a single node in the cluster if -h is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the -h option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using -h.
- Valid compaction types: COMPACTION, VALIDATION, CLEANUP, SCRUB, VERIFY, INDEX_BUILD

**Description**

Stops all compaction operations from continuing to run. This command is typically used to stop a compaction that has a negative impact on the performance of a node. After the compaction stops, Cassandra continues with the remaining operations in the queue. Eventually, Cassandra restarts the compaction.
In Cassandra 2.2 and later, a single compaction operation can be stopped with the -id option. Run `nodetool compactionstats` to find the compaction ID.

**nodetool stopdaemon**

Stops the cassandra daemon.

**Synopsis**

```
$ nodetool <options> stopdaemon
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

**Table 99: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>

</tbody>
</table>

**nodetool tablehistograms**

Provides statistics about a table that could be used to plot a frequency function.

**Synopsis**

```
$ nodetool <options> tablehistograms -- <keyspace> <table>
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

**Table 100: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h</td>
<td>--host</td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Port number.</td>
</tr>
</tbody>
</table>
**Description**

The `nodetool tablehistograms` command provides statistics about a table, including read/write latency, partition size, column count, and number of SSTables. The report is incremental, not cumulative. It covers all operations since the last time `nodetool tablehistograms` was run in the current session. The use of the metrics-core library makes the output more informative and easier to understand.

**Example**

For example, to get statistics about the `libout` table in the `libdata` keyspace, use this command:

```
$ %CASSANDRA_HOME%/bin/nodetool tablehistograms libdata libout
```

**Output:**

```
libdata/libout histograms
Percentile  SSTables  Write Latency  Read Latency  Partition
      Size      Cell Count (micros) (micros)        (bytes)
     (bytes)                    (micros)          (micros)

 50%  1597          42  39.50      36.00
 75%  1597          42  49.00      55.00
 95%  8239         258  95.00      82.00
 98% 17084         446 126.84     110.42
 99% 24601         770 155.13     123.71
```

**Note:** Either `keyspace.table` or `keyspace table` can be used to designate the table.

<td>1110</td>
<td></td>
<td>36</td>
<td></td>
</tr>
<tr>
<td>Max</td>
<td>0.00</td>
<td>50772.00</td>
<td>314.00</td>
</tr>
<tr>
<td>126934</td>
<td></td>
<td>3973</td>
<td></td>
</tr>
</tbody>
</table>

The output shows the percentile rank of read and write latency values, the partition size, and the cell count for the table.

**nodetool tablestats**

Provides statistics about one or more tables.

**Synopsis**

```
$ nodetool [ options ] tablestats
[ -H | --human-readable ]
[ -i table [, table ] . . . ] [ - - ]
[ keyspace | table | keyspace.table ] [keyspace | table | keyspace.table
 ] . . .
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

**Table 101: Options**

<td>Ignore the list of tables and display the remaining tables.</td>
</tr>
</tbody>
</table>

`keyspace.table` List of tables (or keyspace) names.

`--` Separates an option from an argument that could be mistaken for an option.
Description

The `nodetool tablestats` command provides statistics about one or more tables. It's updated when SSTables change through compaction or flushing. Cassandra uses the `metrics-core` library to make the output more informative and easier to understand.

### Table 102: nodetool tablestats output for a single table

### Examples

An excerpt of the output of the command reporting on a library data table just flushed to disk.

```
$ nodetool tablestats keyspace1.standard1
Keyspace: keyspace1
  Read Count: 182849
  Read Latency: 0.11363755339104945 ms.
  Write Count: 435355
  Write Latency: 0.01956930550929701 ms.
  Pending Flushes: 0
  Table: standard1
  SSTable count: 2
  Space used (live): 54131487
  Space used (total): 54131487
  Space used by snapshots (total): 0
  Off heap memory used (total): 309620
  SSTable Compression Ratio: 0.0
  Number of keys (estimate): 376390
  Memtable cell count: 200120
  Memtable data size: 47355786
```
Memtable off heap memory used: 0
Memtable switch count: 2
Local read count: 182849
Local read latency: 0.125 ms
Local write count: 435355
Local write latency: 0.022 ms
Pending flushes: 0
Percent repaired: 100.0%
Bloom filter false positives: 11
Bloom filter false ratio: 0.00009
Bloom filter space used: 272192
Bloom filter off heap memory used: 272176
Index summary off heap memory used: 37444
Compression metadata off heap memory used: 0
Compacted partition minimum bytes: 216
Compacted partition maximum bytes: 258
Compacted partition mean bytes: 258
Average live cells per slice (last five minutes): 1.0
Maximum live cells per slice (last five minutes): 1
Average tombstones per slice (last five minutes): 1.0
Maximum tombstones per slice (last five minutes): 1

Using the human-readable option

Use the human-readable -H option to get output in easier-to-read units. For example:

$ nodetool tablestats -H keyspace1.standard1
Keyspace: keyspace1
Read Count: 182849
Read Latency: 0.11363755339104945 ms.
Write Count: 435355
Write Latency: 0.01956930550929701 ms.
Pending Flushes: 0
Table: standard1
SSTable count: 2
Space used (live): 51.62 MB
Space used (total): 51.62 MB
Space used by snapshots (total): 0 bytes
Off heap memory used (total): 302.36 KB
SSTable Compression Ratio: 0.0
Number of keys (estimate): 376390
Memtable cell count: 200120
Memtable data size: 45.16 MB
Memtable off heap memory used: 0 bytes
Memtable switch count: 2
Local read count: 182849
Local read latency: 0.125 ms
Local write count: 435355
Local write latency: 0.022 ms
Pending flushes: 0
Percent repaired: 100.0%
Bloom filter false positives: 11
Bloom filter false ratio: 0.00000
The location of the `cassandra.yaml` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra.yaml</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra.yaml</code></td>
</tr>
</tbody>
</table>

**nodetool toppartitions**

Samples database reads and writes and reports the most active partitions in a specified table.

**Synopsis**

```
$ nodetool [ options ] toppartitions
[ -a samplers ] [ -k topcount ] [ -s size ] [ -- ]
keyspace table duration
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

**Table 103: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-h</code></td>
<td><code>--host</code></td>
<td>Hostname or IP address.</td>
</tr>
<tr>
<td><code>-p</code></td>
<td><code>--port</code></td>
<td>Port number.</td>
</tr>
<tr>
<td><code>-pwf</code></td>
<td><code>--password-file</code></td>
<td>Password file path.</td>
</tr>
<tr>
<td><code>-pw</code></td>
<td><code>--password</code></td>
<td>Password.</td>
</tr>
<tr>
<td><code>-u</code></td>
<td><code>--username</code></td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td><code>-a samplers</code></td>
<td></td>
<td>Comma separated list of samplers to use (default: all)</td>
</tr>
</tbody>
</table>
### Cassandra tools

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-k</td>
<td>topCount</td>
<td>The number of the top partitions to list (default: 10)</td>
</tr>
<tr>
<td>-s</td>
<td>size</td>
<td>The capacity of stream summary. A value closer to the actual cardinality of partitions yields more accurate results. (default: 256)</td>
</tr>
</tbody>
</table>

**keyspace**  
Name of keyspace.

**table**  
Name of table.

**duration**  
The duration in milliseconds

**--**  
Separates an option from an argument that could be mistaken for a option.

### Description

The `nodetool toppartitions` command samples the activity in a table during the specified duration and prints lists of the most active partitions during that time period. To run this command you must specify the keyspace and table to focus on and the time interval (in milliseconds) during which Cassandra samples the table's activity.

### Examples

Sample the most active partitions for the table `test.users` for 1,000 milliseconds

```
nodetool toppartitions test users 1000
```

The output of `nodetool toppartitions` is similar to the following:

**WRITES Sampler:**

Cardinality: ~2 (256 capacity)  
Top 4 partitions:

<table>
<thead>
<tr>
<th>Partition</th>
<th>Count</th>
<th>+/-</th>
</tr>
</thead>
<tbody>
<tr>
<td>4b504d39354f37353131</td>
<td>15</td>
<td>14</td>
</tr>
<tr>
<td>3738313134394d353530</td>
<td>15</td>
<td>14</td>
</tr>
<tr>
<td>4f363735324e324e4d30</td>
<td>15</td>
<td>14</td>
</tr>
<tr>
<td>303535324e4b4d504c30</td>
<td>15</td>
<td>14</td>
</tr>
</tbody>
</table>

**READS Sampler:**

Cardinality: ~3 (256 capacity)  
Top 4 partitions:

<table>
<thead>
<tr>
<th>Partition</th>
<th>Count</th>
<th>+/-</th>
</tr>
</thead>
<tbody>
<tr>
<td>4d4e30314f374e313730</td>
<td>42</td>
<td>41</td>
</tr>
<tr>
<td>4f363735324e324e4d30</td>
<td>42</td>
<td>41</td>
</tr>
</tbody>
</table>
For each of the samplers used (WRITES and READS in the example), toppartitions reports:

- The cardinality (page) of the sampled operations (that is, the number of unique operations in the sample set)

- The \( n \) partitions in the specified table that had the most traffic in the specified time period (where \( n \) is the value of the \(-k\) argument, or ten if \(-k\) is not explicitly set in the command).

For each Partition, toppartitions reports:

<table>
<thead>
<tr>
<th>Partition</th>
<th>Count</th>
<th>+/-</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition key</td>
<td>The number of operations of the specified type that occurred during the specified time period.</td>
<td>The margin of error for the Count statistic</td>
</tr>
</tbody>
</table>

Note: To keep the toppartitions reporting from slowing performance, Cassandra does not keep an exact count of operations, but uses sampling techniques to create an approximate number. (This example reports on a sample cluster; a production system might generate millions of reads or writes in a few seconds.) The +/- figure allows you to judge the accuracy of the toppartitions reporting.

**nodetool tpstats**

Provides usage statistics of thread pools.

**Synopsis**

```
$ nodetool <options> tpstats
```

**Table 104: Options**

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Port number.</td>
</tr>
<tr>
<td>-pwf</td>
<td>--password-file</td>
<td>Password file path.</td>
</tr>
<tr>
<td>-pw</td>
<td>--password</td>
<td>Password.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Short</th>
<th>Long</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-u</td>
<td>--username</td>
<td>Remote JMX agent username.</td>
</tr>
<tr>
<td></td>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
</tr>
</tbody>
</table>

Description

Cassandra is based on a Staged Event Driven Architecture (SEDA). Cassandra separates different tasks into stages connected by a messaging service. Each stage has a queue and a thread pool. Although some stages skip the messaging service and queue tasks immediately on a different stage when it exists on the same node. Cassandra can back up a queue if the next stage is too busy and lead to a performance bottlenecks.

The `nodetool tpstats` command reports on each stage of Cassandra operations by thread pool:

- The number of Active threads
- The number of Pending requests waiting to be executed by this thread pool
- The number of tasks Completed by this thread pool
- The number of requests that are currently Blocked because the thread pool for the next step in the service is full
- The total number of All-Time Blocked requests, which are all requests blocked in this thread pool up to now.

Reports are updated when SSTables change through compaction or flushing.

Run `nodetool tpstats` on a local node to get statistics for the thread pool used by the Cassandra instance running on that node.

Run `nodetool tpstats` with the appropriate options to check the thread pool statistics for a remote node. For setup instructions, see Secure JMX Authentication (page 126).

`nodetool tpstats` pool names and tasks

This table describes the Cassandra task or property associated with each pool name reported in the `nodetool tpstats` output:

<table>
<thead>
<tr>
<th>Pool Name</th>
<th>Associated tasks</th>
<th>Related information</th>
</tr>
</thead>
<tbody>
<tr>
<td>CacheCleanupExecutor</td>
<td>Clearing the cache</td>
<td></td>
</tr>
<tr>
<td>CommitlogArchiver</td>
<td>Copying or archiving commitlog files for recovery</td>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td>ValidationExecutor</td>
<td>Validating schema</td>
<td></td>
</tr>
</tbody>
</table>

**Cassandra tools**

Cassandra tpstats droppable messages

Cassandra generates the messages listed below, but discards them after a timeout. The nodetool tpstats command reports the number of messages of each type that have been dropped. You can view the messages themselves using a JMX client.

<table>
<thead>
<tr>
<th>Message Type</th>
<th>Stage</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY</td>
<td>n/a</td>
<td>Deprecated</td>
</tr>
<tr>
<td>_TRACE</td>
<td>n/a (special)</td>
<td>Used for recording traces (nodetool settraceprobability) Has a special executor (1 thread, 1000 queue depth) that throws away messages on insertion instead of within the execute</td>
</tr>
<tr>
<td>Message Type</td>
<td>Stage</td>
<td>Notes</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| MUTATION             | MutationStage       | If a write message is processed after its timeout
(write_request_timeout_in_ms)
it either sent a failure to the client or it met its requested consistency level and will relay on hinted handoff and read repairs to do the mutation if it succeeded. |
| COUNTER_MUTATION     | MutationStage       | If a write message is processed after its timeout
(write_request_timeout_in_ms)
it either sent a failure to the client or it met its requested consistency level and will relay on hinted handoff and read repairs to do the mutation if it succeeded. |
| READ_REPAIR          | MutationStage       | Times out after write_request_timeout_in_ms                          |
| READ                 | ReadStage           | Times out after read_request_timeout_in_ms. No point in servicing reads after that point since it would of returned error to client |
| RANGE_SLICE          | ReadStage           | Times out after range_request_timeout_in_ms.                         |
| PAGED_RANGE          | ReadStage           | Times out after request_timeout_in_ms.                               |
| REQUEST_RESPONSE     | RequestResponseStage| Times out after request_timeout_in_ms. Response was completed and sent back but not before the timeout |

**Example**

Running `nodetool tpstats` on the host `labcluster`:

```
$ nodetool -h labcluster tpstats
```

Example output is:

<table>
<thead>
<tr>
<th>Pool Name</th>
<th>Active</th>

nodetool upgradesstables

Rewrites SSTables for tables that are not running the current version of Cassandra. Ensures that the SSTables are compatible with the current version.

Synopsis

$ nodetool <options> upgradesstables
  ( -a | --include-all-sstables )
  -- <keyspace> <table> ...

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

**keyspace** Name of keyspace.

**table** One or more table names, separated by a space.

-- Separates an option from an argument that could be mistaken for a option.

Description
Rewrites SSTables on a node that are incompatible with the current version. Use this command when upgrading your server or changing compression options.

**nodetool verify**

Verify (check data checksum for) one or more tables.

**Synopsis**

```
$ nodetool [options] verify [{-e | --extended-verify}] [--] [<keyspace> <tables>...]
```

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

```
installation_location/resources/cassandra/bin
```

<td>One or more table names, separated by a space.</td>
<td></td>
</tr>
<tr>
<td>--</td>
<td>Separates an option from an argument that could be mistaken for a option.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**

- For tarball installations, execute the command from the `install_location/bin` directory.
- If a username and password for RMI authentication are set explicitly in the `cassandra-env.sh` file for the host, then you must specify credentials.
- `nodetool verify` operates on a single node in the cluster if `-h` is not used to identify one or more other nodes. If the node from which you issue the command is the intended target, you do not need the `-h` option to identify the target; otherwise, for remote invocation, identify the target node, or nodes, using `-h`.

**Description**

The `nodetool verify` command checks the data checksum for one or more specified tables. An optional argument, `-e` or `--extended-verify`, will verify each cell data, whereas without the option, only the SSTable checksums are verified.

**Examples**

```
$ nodetool -u cassandra -pw cassandra verify cycling cyclist_name
```

The location of the `cassandra-env.sh` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Type of Installation</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td><code>/etc/dse/cassandra/cassandra-env.sh</code></td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td><code>install_location/resources/cassandra/conf/cassandra-env.sh</code></td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td><code>/etc/cassandra/cassandra-env.sh</code></td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td><code>install_location/conf/cassandra-env.sh</code></td>
</tr>
</tbody>
</table>

**nodetool version**

Provides the version number of Cassandra running on the specified node.
Synopsis

$ nodetool <options> version

DataStax Enterprise 5.0 Installer No-Services and tarball installations:

installation_location/resources/cassandra/bin

Table 108: Options

<table>

</tbody>
</table>

The cassandra utility

You can run Cassandra 3.0 with start-up parameters by adding them to the cassandra-env.sh file (package or tarball installations). You can also enter parameters at the command line when starting up tarball installations.

The location of the cassandra.yaml (page ) file depends on the type of installation:

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>
<th>/etc/dse/cassandra/cassandra.yaml</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra.yaml</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra.yaml</td>
</tr>
</tbody>
</table>

Usage

Add a parameter to the cassandra-env.sh file as follows:

JVM_OPTS="$JVM_OPTS -D[PARAMETER]"

The location of the cassandra-env.sh file depends on the type of installation:

<table>
<thead>
<tr>
<th>DataStax Enterprise 5.0 Installer-Services and package installations</th>
<th>/etc/dse/cassandra/cassandra-env.sh</th>
</tr>
</thead>
</table>
Cassandra tools

<table>
<thead>
<tr>
<th>Installations</th>
<th>Install Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/cassandra-env.sh</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/cassandra-env.sh</td>
</tr>
</tbody>
</table>

The location of the `jvm.options` file depends on the type of installation:

<table>
<thead>
<tr>
<th>Installations</th>
<th>Install Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/jvm.options</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/jvm.options</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/jvm.options</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/jvm.options</td>
</tr>
</tbody>
</table>

When starting up a tarball installations, you can add parameters at the command line:

```
$ cassandra [PARAMETERS]
```

Examples:
- Command line: `$ bin/cassandra -Dcassandra.load_ring_state=false`
- `cassandra-env.sh`: `JVM_OPTS="$JVM_OPTS -Dcassandra.load_ring_state=false"`

The Example section (page 371) contains more examples.

Command line only options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-f</code></td>
<td>Start the cassandra process in foreground. The default is to start as background process.</td>
</tr>
<tr>
<td><code>-h</code></td>
<td>Help.</td>
</tr>
<tr>
<td><code>-p filename</code></td>
<td>Log the process ID in the named file. Useful for stopping Cassandra by killing its PID.</td>
</tr>
<tr>
<td><code>-v</code></td>
<td>Print the version and exit.</td>
</tr>
</tbody>
</table>

Start-up parameters

The `-D` option specifies start-up parameters at the command line and in the `cassandra-env.sh` file.

- **cassandra.auto_bootstrap=false**
  Sets `auto_bootstrap` (page 99) to `false` on initial set-up of the cluster. The next time you start the cluster, you do not need to change the `cassandra.yaml` file on each node to revert to `true`.

- **cassandra.available_processors=number_of_processors**
  In a multi-instance deployment, each Cassandra instance independently assumes that all CPU processors are available to it. Use this setting to specify a smaller set of processors.

- **cassandra.boot_without_jna=true**
  Configures Cassandra to boot without JNA. If you do not set this parameter to `true`, and JNA does not initialize, Cassandra does not boot.
cassandra.config=
Sets the directory location of the cassandra.yaml file. The default location depends
on the type of installation.

cassandra.expiration_date_overflow_policy=POLICY
Set the policy for TTL (time to live) timestamps that exceed the maximum value
supported by the storage engine, 2038-01-19T03:14:06+00:00. The database
storage engine can only encode TTL timestamps through January 19 2038
03:14:07 UTC due to the Year 2038 problem.

- REJECT: Reject requests that contain an expiration timestamp later than
  2038-01-19T03:14:06+00:00.
- CAP: Allow requests and insert expiration timestamps later than
  2038-01-19T03:14:06+00:00 as 2038-01-19T03:14:06+00:00.

Default: REJECT.

cassandra.ignore_dynamic_snitch_severity=true|false (Default: false)
Setting this property to true causes the dynamic snitch (page 29) to ignore
the severity indicator from gossip when scoring nodes. Severity is a numeric
representation of a node based on compaction events occurring on it, which it
broadcasts via gossip. This factors into the dynamic snitch's formula, unless
overridden.
Future versions will default to true and this setting will be removed. See Failure
detection and recovery (page 21) and Dynamic snitching in Cassandra: past, present,
and future.

cassandra.initial_token=token
Use when Cassandra is not using virtual nodes (vnodes). Sets the initial partitioner
token for a node the first time the node is started. (Default: disabled)

Note: Vnodes automatically select tokens.

cassandra.join_ring=true|false
When set to false, prevents the Cassandra node from joining a ring on startup.
(Default: true) You can add the node to the ring afterwards using nodetool join
(page 295) and a JMX call.

cassandra.load_ring_state=true|false
When set to false, clears all gossip state for the node on restart. (Default: true)

cassandra.metricsReporterConfigFile=file
Enables pluggable metrics reporter. See Pluggable metrics reporting in Cassandra
2.0.2.

cassandra.native_transport_startup_delay_seconds=seconds
Delays the startup of native transport for the number of seconds. (Default: 0)

cassandra.native_transport_port=port
Sets the port on which the CQL native transport listens for clients. (Default: 9042)

cassandra.partitioner=partitioner
Sets the partitioner. (Default: org.apache.cassandra.dht.Murmur3Partitioner)

cassandra.replace_address=listen_address or broadcast_address of dead node
To replace a node that has died, restart a new node in its place specifying the
listen_address (page 87) or broadcast_address (page 100) that the new node is
assuming. The new node must be in the same state as before bootstrapping, without
any data in its data directory.
Cassandra tools

**Note:** The `broadcast_address` defaults to the `listen_address` except when the ring is using the `Ec2MultiRegionSnitch` (page 33).

cassandra.replayList=table
   Allows restoring specific tables from an archived commit log.

cassandra.ring_delay_ms=ms
   Defines the amount of time a node waits to hear from other nodes before formally joining the ring. (Default: 30000ms)

cassandra.rpc_port=port
   Sets the port for the Thrift RPC service, which is used for client connections. (Default: 9160).

cassandra.ssl_storage_port=port
   Sets the SSL port for encrypted communication. (Default: 7001)

cassandra.start_native_transport=true | false
   Enables or disables the native transport server. See `start_native_transport` (page 106) in `cassandra.yaml`. (Default: true)

cassandra.start_rpc=true | false
   Enables or disables the Thrift RPC server. (Default: true)

cassandra.storage_port=port
   Sets the port for inter-node communication. (Default: 7000)

cassandra.triggers_dir=directory
   Sets the default location for the triggers JARs.

   The location of the `triggers` directory depends on the type of installation:

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataStax Enterprise 5.0 Installer-Services and package installations</td>
<td>/etc/dse/cassandra/triggers</td>
</tr>
<tr>
<td>DataStax Enterprise 5.0 Installer-No Services and tarball installations</td>
<td>install_location/resources/cassandra/conf/triggers</td>
</tr>
<tr>
<td>Cassandra package installations</td>
<td>/etc/cassandra/triggers</td>
</tr>
<tr>
<td>Cassandra tarball installations</td>
<td>install_location/conf/triggers</td>
</tr>
</tbody>
</table>

cassandra.write_survey=true
   Enables a tool for testing new compaction and compression strategies to experiment with different strategies and benchmark write performance differences without affecting the production workload. See `Testing compaction and compression` (page 245).

consistent.rangemovement=true
   Set to true, makes bootstrapping behavior effective.

Advanced parameters

DataStax Enterprise provides the following parameters for DSE Authenticator LDAP connections.

dse.ldap.connection.timeout.ms
   The number of milliseconds before the connection times out.
**dse.ldap.pool.min.idle**
Finer control over the connection pool for DataStax Enterprise LDAP authentication connector. The min idle settings determines the minimum number of connections allowed in the pool before the evictor thread will create new connections. This setting has no effect if the evictor thread isn't configured to run.

**dse.ldap.pool.exhausted.action**
Determines what the pool does when it is full. It can be one of:
- **fail** - the pool will throw an exception
- **block** - the pool will block for max wait ms (default)
- **grow** - the pool will just keep growing (not recommended)

**dse.ldap.pool.max.wait**
When the `dse.ldap.pool.exhausted.action` is **block**, sets the number of milliseconds to block the pool before throwing an exception.

**dse.ldap.pool.test.borrow**
Tests a connection when it is borrowed from the pool.

**dse.ldap.pool.test.return**
Tests a connection returned to the pool.

**dse.ldap.pool.test.idle**
Tests any connections in the eviction loop that are not being evicted. Only works if the time between eviction runs is greater than 0ms.

**dse.ldap.pool.time.between.evictions**
Determines the time in ms (milliseconds) between eviction runs. When run with the `dse.ldap.pool.test.idle` this becomes a basic keep alive for connections.

**dse.ldap.pool.num.tests.per.eviction**
Number of connections in the pool that are tested each connection run. If this is set the same as max active (the pool size) then all connections will be tested each eviction run.

**dse.ldap.pool.min.evictable.idle.time.ms**
Determines the minimum time in ms (milliseconds) that a connection can sit in the pool before it becomes available for eviction.

**dse.ldap.pool.soft.min.evictable.idle.time.ms**
Determines the minimum time in ms (milliseconds) that a connection can sit the pool before it becomes available for eviction with the proviso that the number of connections doesn't fall below `dse.ldap.pool.min.evictable.idle.time.ms`.

**Tip:** You can also add options such as maximum and minimum heap size to the `cassandra-env.sh` file to pass them to the Java virtual machine at startup, rather than setting them in the environment.

**Clearing gossip state when starting a node:**
- **Command line:** `$ bin/cassandra -Dcassandra.load_ring_state=false`
- **cassandra-env.sh:** `JVM_OPTS="$JVM_OPTS -Dcassandra.load_ring_state=false"`
Starting a Cassandra node without joining the ring:

- **Command line:** `bin/dse cassandra -Dcassandra.join_ring=false #Starts DataStax Enterprise`
- **cassandra-env.sh:** `JVM_OPTS="$JVM_OPTS -Dcassandra.join_ring=false"

Replacing a dead node:

- **Command line:**
  
  ```
  $ bin/dse cassandra -Dcassandra.replace_address=10.91.176.160 #Starts DataStax Enterprise
  ```

  - **cassandra-env.sh:** `JVM_OPTS="$JVM_OPTS -Dcassandra.replace_address=10.91.176.160"

The cassandra-stress tool

The **cassandra-stress** tool is a Java-based stress testing utility for basic benchmarking and load testing a Cassandra cluster.

Data modeling choices can greatly affect application performance. Significant load testing over several trials is the best method for discovering issues with a particular data model. The **cassandra-stress** tool is an effective tool for populating a cluster and stress testing CQL tables and queries. Use **cassandra-stress** to:

- Quickly determine how a schema performs.
- Understand how your database scales.
- Optimize your data model and settings.
- Determine production capacity.

The **cassandra-stress** tool also supports a YAML-based profile for defining specific schemas with various compaction strategies, cache settings, and types. Sample files are located in:

- **Cassandra package installations:** `/usr/share/docs/cassandra/examples`
- **Cassandra tarball installations:** `install_location/tools/

The YAML file supports user-defined keyspace, tables, and schema. The YAML file can be used to design tests of reads, writes, and mixed workloads.

When started without a YAML file, **cassandra-stress** creates a keyspace, keyspace1, and tables, standard1 or counter1, depending on what type of table is being tested. These elements are automatically created the first time you run a stress test and reused on subsequent runs. You can drop keyspace1 using **DROP KEYSSPACE** (page ). You
cannot change the default keyspace and tables names without using a YAML file (page 381).

Usage:

- **DataStax Enterprise 5.0 Installer Services and package installations:**

  
  $ cassandra-stress command [options]

- **DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

  
  $ cd install_location/resources/cassandra/tools
  $ bin/cassandra-stress command [options]

- **Cassandra package installations:**

  
  $ cassandra-stress command [options]

- **Cassandra tarball installations:**

  
  $ cd install_location/tools
  $ bin/cassandra-stress command [options]

When entering the `help` command, be sure to precede the option name with a hyphen, as shown.

### Cassandra-stress sub-options

<table>
<thead>
<tr>
<th>Sub-option</th>
<th>Description</th>
</tr>
</thead>
</table>
| `-col`      | Column details, such as size and count distribution, data generator, names, and comparator.  
**Usage:**  
- `-col names=? [slice] [super=?] [comparator=?] [timestamp=?] [size=DIST(?)]`  
or  
- `-col [n=DIST(?)] [slice] [super=?] [comparator=?] [timestamp=?] [size=DIST(?)]` |
| `-errors`   | How to handle errors when encountered during stress testing.  
**Usage:**  
- `-errors [retries=?] [ignore] [skip-read-validation]`  
  - `retries=N` Number of times to try each operation before failing.  
  - `ignore` Do not fail on errors.  
  - `skip-read-validation` Skip read validation and message output. |
| `-graph`    | Graph results of cassandra-stress tests. Multiple tests can be graphed together.  
**Usage:**  
- `-graph file=? [revision=?] [title=?] [op=?]` |
| `-insert`   | Insert specific options relating to various methods for batching and splitting partition updates.  
**Usage:**  
- `-insert [revisit=DIST(?)] [visits=DIST(?)] partitions=DIST(?) [batchtype=?] select-ratio=DIST(?) row-population-ratio=DIST(?)` |
| `-log`      | Where to log progress and the interval to use.  
**Usage:**  
- `-log [level=?] [no-summary] [file=?] [interval=?]` |
<table>
<thead>
<tr>
<th>Sub-option</th>
<th>Description</th>
</tr>
</thead>
</table>
| **-mode**  | Thrift or CQL with options.  
  **Usage:**  
  `-mode thrift [smart] [user=?] [password=?]`  
  or  
  `-mode native [unprepared] cql3 [compression=?] [port=?] [user=?] [password=?] [auth-provider=?] [maxPending=?] [connectionsPerHost=?]`  
  or  
  `-mode simplenative [prepared] cql3 [port=?]` |
| **-node**  | Nodes to connect to.  
  **Usage:**  
  `-node [whitelist] [file=?]` |
| **-pop**   | Population distribution and intra-partition visit order.  
  **Usage:**  
  `-pop seq=? [no-wrap] [read-lookback=DIST(?)]) [contents=?]`  
  or  
  `-pop [dist=DIST(?)]) [contents=?]` |
| **-port**  | Specify port for connecting Cassandra nodes. Port can be specified for Cassandra native protocol, Thrift protocol or a JMX port for retrieving statistics.  
  **Usage:**  
  `-port [native=?] [thrift=?] [jmx=?]` |
<table>
<thead>
<tr>
<th>Sub-option</th>
<th>Description</th>
</tr>
</thead>
</table>
| **-rate**  | Set the rate using the following options:  
|            | `-rate threads=N [throttle=N] [fixed=N]`  
|            | where:  
|            | • `threads=N` number of clients to run concurrently.  
|            | • `throttle=N` throttle operations per second across all clients to a maximum rate (or less) with no implied schedule. Default is 0.  
|            | • `fixed=N` expect fixed rate of operations per second across all clients with implied schedule. Default is 0.  
| OR         | `-rate [threads>=N] [threads<=N] [auto]`  
|            | Where:  
|            | • `threads>=N` run at least this many clients concurrently. Default is 4.  
|            | • `threads<=N` run at most this many clients concurrently. Default is 1000.  
|            | • `auto` stop increasing threads once throughput saturates.  

| **-sample** | Specify the number of samples to collect for measuring latency.  
| **Usage:**  | `-sample [history=?] [live=?] [report=?]`  

| **-schema** | Replication settings, compression, compaction, and so on.  
| **Usage:**  | `-schema [replication(?)] [keyspace=?] [compaction(?)] [compression=?]`  

| **-sendto** | Specify a stress server to send this command to.  
| **Usage:**  | `-sendToDaemon <host>`  

| **-transport** | Custom transport factories.  
| **Usage:**  | `-transport [factory=?] [truststore=?] [truststore-password=?] [ssl-protocol=?] [ssl-alg=?] [store-type=?] [ssl-ciphers=?]`  

Additional command-line parameters can modify how cassandra-stress runs:

Additional cassandra-stress parameters
<table>

</tbody>
</table>

Example: Simple read and write examples

```
# Insert (write) one million rows
$ cassandra-stress write n=1000000 -rate threads=50

# Read two hundred thousand rows.
$ cassandra-stress read n=200000 -rate threads=50

# Read rows for a duration of 3 minutes.
$ cassandra-stress read duration=3m -rate threads=50

# Read 200,000 rows without a warmup of 50,000 rows first.
$ cassandra-stress read n=200000 no-warmup -rate threads=50
```

Example: View schema help

```
$ cassandra-stress help -schema
```
Cassandra tools

replication([strategy=?] [factor=?] [<option 1..N>=?]):
  Define the replication strategy and any parameters
  strategy=? (default=org.apache.cassandra.locator.SimpleStrategy)
  The replication strategy to use
  factor=? (default=1)
  The number of replicas
  keyspace=? (default=keyspace1)
  The keyspace name to use

compaction([strategy=?] [<option 1..N>=?]):
  Define the compaction strategy and any parameters
  strategy=?
  The compaction strategy to use
  compression=?
  Specify the compression to use for SSTable, default:no compression

Example: Populate the database

Generally it is easier to let cassandra-stress create the basic schema and then modify it in CQL (page ):

#Load one row with default schema
$ cassandra-stress write n=1 cl=one -mode native cql3 -log file=create_schema.log

#Modify schema in CQL
$ cqlsh

#Run a real write workload
$ cassandra-stress write n=1000000 cl=one -mode native cql3 -schema keyspace="keyspace1" -log file=load_1M_rows.log

Example: Change the replication strategy

Changes the replication strategy to NetworkTopologyStrategy and targets one node named existing.

$ cassandra-stress write n=500000 no-warmup -node existing -schema "replication(strategy=NetworkTopologyStrategy, existing=2)"

Example: Run a mixed workload

When running a mixed workload, you must escape parentheses, greater-than and less-than signs, and other such things. This example invokes a workload that is one-quarter writes and three-quarters reads.
Notice the following in this example:

1. The ratio parameter requires backslash-escaped parenthesis.

2. The value of \( n \) used in the read phase is different from the value used in write phase. During the write phase, \( n \) records are written. However in the read phase, if \( n \) is too large, it is inconvenient to read all the records for simple testing. Generally, \( n \) does not need be large when validating the persistent storage systems of a cluster.

   The \(-pop\ dist=UNIFORM\(1..1000000\)\) portion says that of the \( n=100,000 \) operations, select the keys uniformly distributed between 1 and 1,000,000. Use this when you want to specify more data per node than what fits in DRAM.

3. In the rate section, the greater-than and less-than signs are escaped. If not escaped, the shell attempts to use them for IO redirection: the shell tries to read from a non-existent file called \( =256 \) and create a file called \( =16 \). The rate section tells cassandra-stress to automatically attempt different numbers of client threads and not test less that 16 or more than 256 client threads.

Example: Standard mixed read/write workload keyspace for a single node

```
CREATE KEYSPACE "keyspace1" WITH replication = {
'class': 'SimpleStrategy',
'replication_factor': '1'};
USE "keyspace1";
CREATE TABLE "standard1" (key blob,
"C0" blob,
"C1" blob,
"C2" blob,
"C3" blob,
"C4" blob,
PRIMARY KEY (key))
) WITH
bloom_filter_fp_chance=0.010000 AND
caching='KEYS_ONLY' AND
cmment='' AND
dclocal_read_repair_chance=0.000000 AND
gc_grace_seconds=864000 AND
index_interval=128 AND
read_repair_chance=0.100000 AND
```

Apache Cassandra 3.0 for DSE 5.0 (Earlier version)
Cassandra tools

```
replicate_on_write='true' AND
default_time_to_live=0 AND
speculative_retry='99.0PERCENTILE' AND
memtable_flush_period_in_ms=0 AND
compaction={'class': 'SizeTieredCompactionStrategy'} AND
compression={'class': 'LZ4Compressor'};
```

Example: Split up a load over multiple cassandra-stress instances on different nodes

This example demonstrates loading into large clusters, where a single `cassandra-stress` load generator node cannot saturate the cluster. In this example, `$NODES` is a variable whose value is a comma delimited list of IP addresses such as 10.0.0.1, 10.0.0.2, and so on.

```bash
# On Node1
$ cassandra-stress write n=1000000 cl=one -mode native cql3 -schema keyspace="keyspace1" -pop seq=1..1000000 -log file=~/.node1_load.log -node $NODES

# On Node2
$ cassandra-stress write n=1000000 cl=one -mode native cql3 -schema keyspace="keyspace1" -pop seq=1000001..2000000 -log file=~/.node2_load.log -node $NODES
```

Example: Run cassandra-stress with authentication

The following example shows using the `-mode` option to supply a username and password:

```bash
$ cassandra-stress -mode native cql3 user=cassandra password=cassandra no-warmup cl=QUORUM
```

**Note:** Check the documentation of the `transport` option for SSL authentication.

Example: Run cassandra-stress with authentication and SSL encryption

The following example shows using the `-mode` option to supply a username and password, and the `-transportation` option for SSL parameters:

```bash
$ cassandra-stress write n=100k cl=ONE no-warmup -mode native cql3 user=cassandra password=cassandra
```
keystore=/usr/local/lib/dsc-cassandra/conf/server-keystore.jks
keystore-password=myKeyPass

**Note:** Cassandra authentication and SSL encryption must already be configured (page 117) before executing `cassandra-stress` with these options. The example shown above uses self-signed CA certificates (page 134).

Example: Run `cassandra-stress` using the truncate option

This option must be inserted before the `mode` option, otherwise the `cassandra-stress` tool won't apply truncation as specified.

The following example shows the `truncate` command:

```
$ cassandra-stress write n=10000000 cl=QUORUM truncate=always -
    schema keyspace=keyspace-rate threads=200 -log file=write_$NOW.log
```

Example: Use a YAML file to run `cassandra-stress`

This example uses a YAML file named `cqlstress-example.yaml`, which contains the keyspace and table definitions, and a query definition. The keyspace name and definition are the first entries in the YAML file:

```
keyspace: perftesting
keyspace_definition:

    CREATE KEYSPACE perftesting WITH replication = {
        'class': 'SimpleStrategy',
        'replication_factor': 3};
```

The table name and definition are created in the next section using CQL:

```
table: users
table_definition:

    CREATE TABLE users (username text,
        first_name text,
        last_name text,
        password text,
        email text,
        last_access timeuuid,
        PRIMARY KEY(username)
    );
```
In the `extra_definitions` section you can add secondary indexes or materialized views to the table:

```plaintext
extra_definitions:
- CREATE MATERIALIZED VIEW perftesting.users_by_first_name AS 
  SELECT * FROM perftesting.users WHERE first_name IS NOT NULL and username IS NOT NULL PRIMARY KEY (first_name, username);
- CREATE MATERIALIZED VIEW perftesting.users_by_first_name2 AS 
  SELECT * FROM perftesting.users WHERE first_name IS NOT NULL and username IS NOT NULL PRIMARY KEY (first_name, username);
- CREATE MATERIALIZED VIEW perftesting.users_by_first_name3 AS 
  SELECT * FROM perftesting.users WHERE first_name IS NOT NULL and username IS NOT NULL PRIMARY KEY (first_name, username);
```

The population distribution can be defined for any column in the table. This section specifies a uniform distribution between 10 and 30 characters for `username` values in generated rows, a uniform distribution between 20 and 40 characters for generated `startdate` over the entire DSE cluster, and a Gaussian distribution between 100 and 500 characters for `description` values.

```plaintext
columnspec:
- name: username
  size: uniform(10..30)
- name: first_name
  size: fixed(16)
- name: last_name
  size: uniform(1..32)
- name: password
  size: fixed(80) # sha-512
- name: email
  size: uniform(16..50)
- name: startdate
  cluster: uniform(20...40)
- name: description
  size: gaussian(100...500)
```

After the column specifications, you can add specifications for how each batch runs. In the following code, the `partitions` value directs the test to use the column definitions above to insert a fixed number of rows in the partition in each batch:

```plaintext
insert:
  partitions: fixed(10)
  batchtype: UNLOGGED
```

The last section contains a query, `read1`, that can be run against the defined table.

```plaintext
queries:
  read1:
    cql: select * from users where username = ? and startdate = ?
```
The following example shows using the `user` option and its parameters to run `cassandra-stress` tests from `cqlstress-example.yaml`:

```
$ cassandra-stress user profile=tools/cqlstress-example.yaml
n=1000000 ops\(insert=3,read1=1\) no-warmup cl=QUORUM
```

Notice that:

- The `user` option is required for the `profile` and `opt` parameters.
- The value for the `profile` parameter is the path and filename of the .yaml file.
- In this example, `–n` specifies the number of `batches` that run.
- The values supplied for `ops` specifies which operations run and how many of each. These values direct the command to insert rows into the database and run the `read1` query.

How many times? Each insert or query counts as one batch, and the values in `ops` determine how many of each type are run. Since the total number of batches is 1,000,000, and `ops` says to run three inserts for each query, the result will be 750,000 inserts and 250,000 of the `read1` query.

Use escaping backslashes when specifying the `ops` value.

For more information, see Improved Cassandra 2.1 Stress Tool: Benchmark Any Schema – Part 1.

Example: Use the `-graph` option

In Cassandra 3.2 and later, the `-graph` option provides visual feedback for `cassandra-stress` tests. A file must be named to build the resulting HTML file. A `title` and `revision` are optional, but `revision` must be used if multiple stress tests are graphed on the same output.

```
$ cassandra-stress user profile=tools/cqlstress-example.yaml ops \(insert=1\) -graph file=test.html title=test revision=test1
```

An interactive graph can be displayed with a web browser:
Interpreting the output of cassandra-stress

Each line reports data for the interval between the last elapsed time and current elapsed time.

Created keyspaces. Sleeping 1s for propagation.
Sleeping 2s...
Warming up WRITE with 50000 iterations...
Running WRITE with 200 threads for 1000000 iterations

## SSTable utilities

### sstabledump

This tool outputs the contents of the specified SSTable in the JSON format.

Depending on your task, you may wish to flush the table to disk (using `nodetool flush (page 279)` before dumping its contents.

**Usage:**

- **DataStax Enterprise 5.0 Installer Services and package installations:**
  ```
  $ sstabledump [options] sstable_file
  ```

- **DataStax Enterprise 5.0 Installer No-Services and tarball installations:**
  ```
  $ cd install_location/resources/cassandra/tools
  $ bin/sstablekeys <sstable_name>
  ```

- **Cassandra package installations:**
  ```
  $ sstabledump [options] sstable_file
  ```

- **Cassandra tarball installations:**
  ```
  $ cd install_location/tools
  $ bin/sstabledump [options] sstable_file
  ```

The file is located in the data directory and has a .db extension.

- **DataStax Enterprise 5.0 Installer-Services and package installations:** /var/lib/cassandra/data
- **DataStax Enterprise 5.0 Installer-No Services and tarball installations:** /var/lib/cassandra/data
- **Cassandra package installations:** /var/lib/cassandra/data
- **Cassandra tarball installations:** install_location/data/data

### Table 110: Options

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-d</td>
<td>Outputs an internal representation, one CQL row per line.</td>
</tr>
<tr>
<td>-e</td>
<td>Limits output to the list of keys.</td>
</tr>
<tr>
<td>Flag</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>-k key</td>
<td>Limits output to information about the row identified by the specified key.</td>
</tr>
<tr>
<td>-x key</td>
<td>Excludes information about the row identified by the specified key from output.</td>
</tr>
</tbody>
</table>

### sstableexpiredblockers

During compaction, Cassandra can drop entire SSTables if they contain only expired tombstones and if it is guaranteed to not cover any data in other SSTables. This diagnostic tool outputs all SSTables that are blocking other SSTables from being dropped.

Usage:

- **DataStax Enterprise 5.0 Installer Services and package installations:**
  
  ```
  $ sstableexpiredblockers [--dry-run] keyspace table
  ```

- **DataStax Enterprise 5.0 Installer No-Services and tarball installations:**
  
  ```
  $ cd install_location/resources/cassandra/tools
  $ bin/sstableexpiredblockers [--dry-run] keyspace table
  ```

- **Cassandra package installations:**
  
  ```
  $ sstableexpiredblockers [--dry-run] keyspace table
  ```

- **Cassandra tarball installations:**
  
  ```
  $ cd install_location/tools
  $ bin/sstableexpiredblockers [--dry-run] keyspace table
  ```

1. Choose a keyspace and table to check for any SSTables that are blocking the specified table from dropping.

  ```
  $ sstableexpiredblockers cycling cyclist_name
  ```

### sstablelevelreset

Reset level to 0 on a given set of SSTables that use LeveledCompactionStrategy.

Usage:

- **DataStax Enterprise 5.0 Installer Services and package installations:**
  
  ```
  $ sstablelevelreset [--really-reset] keyspace table
  ```

- **DataStax Enterprise 5.0 Installer No-Services and tarball installations:**
  
  ```
  $ cd install_location/resources/cassandra/tools
  $ bin/sstablelevelreset [--really-reset] keyspace table
  ```
Cassandra tools

- Cassandra package installations:

  ```
  $ sstablelevelreset [--really-reset] keyspace table
  ```

- Cassandra tarball installations:

  ```
  $ cd install_location/tools
  $ bin/sstablelevelreset [--really-reset] keyspace table
  ```

  The option `--really-reset` is a warning that Cassandra is stopped before the tool is run.

- Stop Cassandra on the node. Choose a keyspace and table to reset to level 0.

  ```
  $ sstablelevelreset --really-reset cycling cyclist_name
  ```

  If the designated table is already at level 0, then no change occurs. If the SSTable is releveled, the metadata is rewritten to designate the level to 0.

**sstableloader (Cassandra bulk loader)**

The Cassandra bulk loader, also called the sstableloader, provides the ability to:

- Bulk load external data into a cluster.
- Load existing SSTables into another cluster with a different number of nodes or replication strategy.
- Restore snapshots.

The `sstableloader` streams a set of SSTable data files to a live cluster. It does not simply copy the set of SSTables to every node, but transfers the relevant part of the data to each node, conforming to the replication strategy of the cluster. The table into which the data is loaded does not need to be empty.

**Warning:** Running the `sstableloader` against the live data directory can cause snapshots to fail. Specify the snapshots directory when running the `sstableloader`.

In the `/var/lib/cassandra/data` directory, select a keyspace and a table to access the associated snapshots directory, as shown in the following example.

```
$ cd /var/lib/cassandra/data/keyspace/table_name/snapshots/snapshot_name
```

Run `sstableloader` specifying the path to the SSTables and passing it the location of the target cluster. When using the `sstableloader` be aware of the following:

- Bulkloading SSTables created in versions prior to Cassandra 3.0.0 is supported only in Cassandra 3.0.5 and later.
- Repairing tables that have been loaded into a different cluster does not repair the source tables.

**Prerequisites:**
• The source data loaded by `sstableloader` must be in SSTables.
• Because `sstableloader` uses the streaming protocol, it requires a direct connection over the port 7000 (storage port) to each connected node.

Generating SSTables

When using `sstableloader` to load external data, you must first put the external data into SSTables.

`SSTableWriter` is the API to create raw Cassandra data files locally for bulk load into your cluster. The Cassandra source code includes the `CQLSSTableWriter` implementation for creating SSTable files from external data without needing to understand the details of how those map to the underlying storage engine. Import the `org.apache.cassandra.io.sstable.CQLSSTableWriter` class, and define the schema for the data you want to import, a writer for the schema, and a prepared insert statement. For a complete example, see https://www.datastax.com/dev/blog/using-the-cassandra-bulk-loader-updated.

Restoring Cassandra snapshots

For information about preparing snapshots for `sstableloader` import, see Restoring from centralized backups (page 206).

Importing SSTables from an existing cluster

Before importing existing SSTables, run `nodetool flush` (page 279) on each source node to assure that any data in memtables is written out to the SSTables on disk.

Preparing the target environment

Before loading the data, you must define the schema of the target tables with CQL (page ) or Thrift.

Usage

• DataStax Enterprise 5.0 Installer Services and package installations:

  $ sstableloader -d host_url (,host_url ...) [options] path_to_keyspace

• DataStax Enterprise 5.0 Installer No-Services and tarball installations:

  $ cd install_location/resources/cassandra
  $ bin/sstableloader -d host_url (,host_url ...) [options] path_to_keyspace

• Cassandra package installations:

  $ sstableloader -d host_url (,host_url ...) [options] path_to_keyspace

• Cassandra tarball installations:

  $ cd install_location
The **sstableloader** bulk loads the SSTables found in the specified directory, where the parent directories of the path are used for the target keyspace and table name, to the indicated target cluster.

Verify the location of the sstables to be streamed ends with directories named for the keyspace and table:

```
$ ls /var/lib/cassandra/data/Keyspace1/Standard1/snapshot/snapshot_name
Keyspace1-Standard1-jb-60-CRC.db
Keyspace1-Standard1-jb-60-Data.db
...
Keyspace1-Standard1-jb-60-TOC.txt
```

For more **sstableloader** options, see [sstableloader options](page 391)

Using **sstableloader**

1. If restoring snapshot data from some other source: make sure that the snapshot files are in a `keyspace/tablename/snapshot/snapshot_name` directory path whose names match those of the target `keyspace/tablename/snapshot/snapshot_name`. In this example, make sure the snapshot files are in `/Keyspace/Standard1/snapshot/snapshot_name`.

2. Go to the location of the SSTables:

    DataStax Enterprise and Cassandra package installations:

    ```
    $ cd /var/lib/cassandra/data/Keyspace1/Standard1/snapshot/snapshot_name
    ```

    Cassandra tarball installations

    ```
    $ cd install_location/data/data/Keyspace1/Standard1/snapshot/snapshot_name
    ```

3. To view the contents of the keyspace:

    ```
    $ ls
    ```

    ```
    Keyspace1-Standard1-jb-60-CRC.db
    Keyspace1-Standard1-jb-60-Data.db
    ...
    Keyspace1-Standard1-jb-60-TOC.txt
    ```

4. To bulk load the files, **indicate one or more nodes in the target cluster with the -d flag**, which takes a comma-separated list of IP addresses or hostnames, and
specify the path to ..//Keyspace1/Standard1/snapshot/snapshot_name in the source machine. For example:

$ sstableloader -d 110.82.155.1 /var/lib/cassandra/data/Keyspace1/Standard1/snapshot/snapshot_name

This command bulk loads all files.

Note: To get the best throughput from SSTable loading, you can use multiple instances of sstableloader to stream across multiple machines. No hard limit exists on the number of SSTables that sstableloader can run at the same time, so you can add additional loaders until you see no further improvement.

Usage

$ sstableloader -d host_url (... [options] path_to_keyspace

Table 111: sstableloader options

<table>
<thead>
<tr>
<th>Short option</th>
<th>Long option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-alg</td>
<td>--ssl-alg &lt;ALGORITHM&gt;</td>
<td>Client SSL algorithm (default: SunX509).</td>
</tr>
<tr>
<td>-ap</td>
<td>--auth-provider &lt;auth provider class name&gt;</td>
<td>Allows the use of a third party auth provider. Can be combined with -u &lt;username&gt; and -pw &lt;password&gt; if the auth provider supports plain text credentials.</td>
</tr>

<td>Client SSL. Password of the truststore.</td>
</tr>
<tr>
<td>-u</td>
<td>--username &lt;username&gt;</td>
<td>User name for authentication.</td>
</tr>
<tr>
<td>-v</td>
<td>--verbose</td>
<td>Verbose output.</td>
</tr>
</tbody>
</table>

The location of the cassandra.yaml (page ) file depends on the type of installation:
sstablemetadata

The sstablemetadata utility prints metadata about a specified SSTable, including:

- SSTable name
- partitioner
- SSTable level (for Leveled Compaction (page 43) only)
- number of tombstones and Dropped timestamps (in epoch time)
- number of cells and size (in bytes) per row

Use this report to troubleshoot wide rows or performance-degrading tombstones.

Usage

- DataStax Enterprise 5.0 Installer Services and package installations:
  ```
  $ sstablemetadata <sstable_name filenames>
  ```

- Cassandra tarball installations:
  ```
  $ cd install_location/resources/cassandra/tools
  $ bin/sstablemetadata <sstable_name filenames>
  ```

- Cassandra package installations:
  ```
  $ sstablemetadata <sstable_name filenames>
  ```

- Cassandra tarball installations:
  ```
  $ cd install_location/tools
  $ bin/sstablemetadata <sstable_name filenames>
  ```

1. Enter the command sstablemetadata followed by the filenames of one or more SSTables.

```bash
$ sstablemetadata <sstable_name filenames>
```

```
tools/bin/sstablemetadata  data/data/autogeneratedtest/

</table>
sstableofflinerelevel

This tool is intended to run in an offline fashion. When using the LevelledCompactionStrategy, it is possible for the number of SSTables in level L0 to become excessively large, resulting in read latency degrading. This is often the case when atypical write load is experienced (e.g. bulk import of data, node bootstrapping). This tool will relevel the SSTables in an optimal fashion. The --dry run flag can be used to run in test mode and examine the tools results.

Usage:

- DataStax Enterprise 5.0 Installer Services and package installations:

  $ sstableofflinerelevel [--dry-run] keyspace table

- DataStax Enterprise 5.0 Installer No-Services and tarball installations:

  $ cd install_location//resources/cassandra/tools
  $ bin/sstableofflinerelevel [--dry-run] keyspace table

- Cassandra package installations:

  $ sstableofflinerelevel [--dry-run] keyspace table

- Cassandra tarball installations:

  $ cd install_location/tools
  $ bin/sstableofflinerelevel [--dry-run] keyspace table

1. Choose a keyspace and table to relevel.

  $ sstableofflinerelevel cycling cyclist_name

sstablepartitions

Identifies large partitions of SSTables and generate output in JSON format. The output includes the partition size, row count, cell count, and tombstone count.

Synopsis

```
$ sstablepartitions
[-b] [-c cell_count_threshold] [-k partition_keys] [-m]
[-o tombstone_count_threshold] [-r] [-t partition_count_threshold]
[-u] [-x partition_keys] [-y] sstable_name|sstable_directory
```
### Table 112: Legend

<tr>
<td>@xml_entity='xml_entity_type'</td>
<td>Search CQL only: Identify the entity and literal value to overwrite the XML element in the schema and solrconfig files.</td>
</tr>
</tbody>
</table>

Identifies large partitions of the specified SSTable or directory and outputs the partition size, row count, cell count, and tombstone count, where:

**sstable_name**
- The name of the SSTable file. Specify *sstable_name* or *sstable_directory*.

**sstable_directory**
- The data directory.

**-b,**--backups
- Include backups in the data directories (recursive scans).

**-c cell_count_threshold,**--min-cells **cell_count_threshold**
Partition cell count threshold. When this threshold for cell count is exceeded, identify as a large partition.

-k partition_keys,--key partition_keys
   Include partition keys.

-m,--csv
   Instead of JSON formatted output, produce CSV machine-readable output.

-o tombstone_count_threshold,--min-tombstones tombstone_count_threshold
   Partition tombstone count threshold.

-r,--recursive
   Scan for SSTables recursively.

-s,--snapshots
   Include snapshots present in data directories (recursive scans).

-t partition_count_threshold,--min-size partition_count_threshold
   Partition size threshold.

-u,--current-timestamp
   Include timestamp in output. Timestamp is the number seconds since epoch, unit time for TTL expired calculation.

-x partition_keys,--exclude-key partition_keys
   Exclude partition key or keys from partition detailed row/cell/tombstone information. Does not apply if -y option is given.

-y,--partitions-only
   Provide brief partition information only. Exclude per-partition detailed row/cell/tombstone information from process and output.

Examples

Analyze partition statistics for all SSTables a single table

**sstablerepairedset**

This tool is intended to mark specific SSTables as **repaired** or **unrepaired**. It is used to set the **repairedAt** status on a given set of SSTables. This metadata facilitates incremental repairs. It can take in the path to an individual SSTable or the path to a file containing a list of SSTables paths.

**Warning:** Do not run this command until you have stopped Cassandra on the node.

Use this tool in the process of migrating a Cassandra installation to incremental repair *(page 222)*.

**Usage:**

- **DataStax Enterprise 5.0 Installer Services and package installations:**

  ```bash
  $ sstablerepairedset [--really-set] [--is-repaired | --is-unrepaired]
  [-f sstable-list | sstables]
  ```

- **DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

  ```bash
  $ cd install_location/resources/cassandra/tools
  $ bin/stablerepairedset [--really-set] [--is-repaired | --is-unrepaired]
  [-f sstable-list | sstables]
  ```

- **Cassandra package installations:**

  ```bash
  ```
Cassandra tools

```
$ sstablerepairedset [--really-set] [--is-repaired | --is-unrepaired]
[ -f sstable-list | sstables]
```

- **Cassandra tarball installations:**

  ```
  $ cd install_location/tools
  $ bin/sstablerepairedset [--really-set] [--is-repaired | --is-unrepaired]
  [ -f sstable-list | sstables]
  ```

- **Choose SSTables to mark as repaired.**

  ```
  $ sstablerepairedset --really-set --is-repaired
data/data/cycling/
cyclist_name-a882dca02aaf11e58c7b8b496c707234/la-1-big-Data.db
  ```

- **Use a file to list the SSTable to mark as unrepaired.**

  ```
  $ /sstablerepairedset --is-unrepaired -f repairSetSSTables.txt
  ```

  A file like `repairSetSSTables.txt` would contain a list of SSTable (.db) files, as in the following example:

  ```
  /data/data/cycling/
cyclist_by_country-82246fc065ff11e5a4c58b496c707234/ma-1-big-Data.db
  /data/data/cycling/
cyclist_by_birthday-8248246065ff11e5a4c58b496c707234/ma-1-big-
  Data.db
  /data/data/cycling/
cyclist_by_birthday-8248246065ff11e5a4c58b496c707234/ma-2-big-
  Data.db
  /data/data/cycling/cyclist_by_age-8201305065ff11e5a4c58b496c707234/
  ma-1-big-Data.db
  /data/data/cycling/cyclist_by_age-8201305065ff11e5a4c58b496c707234/
  ma-2-big-Data.db
  ```

  Use the following command to list all the Data.db files in a keyspace:

  ```
  $ find '/home/user/apache-cassandra-3.0.2/data/data/keyspace1/' -iname "*Data.db*"
  ```

**sstablescrub**

The sstablescrub utility is an offline version of `nodetool scrub` *(page 320)*. It attempts to remove the corrupted parts while preserving non-corrupted data. Because sstablescrub runs offline, it can correct errors that `nodetool scrub` cannot. If an SSTable cannot be read due to corruption, it will be left on disk.

If scrubbing results in dropping rows, new SSTables become unrepaired. However, if no bad rows are detected, the SSTable keeps its original `repairedAt` field, which denotes the time of the repair.
1. Before using `sstablescrub`, try rebuilding the tables using `nodetool scrub`. If `nodetool scrub` does not fix the problem, use this utility.

2. Shut down the node *(page 176)*.

3. Run the utility:
   - DataStax Enterprise 5.0 Installer Services and package installations:
     ```
     $ sstablescrub [options] keyspace table
     ```
   - DataStax Enterprise 5.0 Installer No-Services and tarball installations:
     ```
     $ cd install_location/resources/cassandra
     $ bin/sstablescrub [options] keyspace table
     ```
   - Cassandra package installations:
     ```
     $ sstablescrub [options] keyspace table
     ```
   - Cassandra tarball installations:
     ```
     $ cd install_location
     $ bin/sstablescrub [options] keyspace table
     ```

   - `--debug`
     Display stack traces.
   - `--help`
     Display help.
   - `--manifest-check`
     Only check and repair the leveled manifest, without actually scrubbing the SSTables.
   - `--reinsert-overflowed-ttl`
     Rewrite SSTables containing rows with overflowed expiration time with the maximum expiration date of `2038-01-19T03:14:06+00:00` using the original timestamp + 1 (ms).
   - `--skip-corrupted`
     Skip corrupted rows in counter tables.
   - `--verbose`
     Verbose output.

`sstablesplit`

Use this tool to split SSTables files into multiple SSTables of a maximum designated size. For example, if SizeTieredCompactionStrategy was used for a major compaction and results in an excessively large SSTable, it's a good idea to split the table because won't get compacted again until the next huge compaction.
Cassandra tools

Cassandra must be stopped to use this tool:

- **Cassandra package installations:**
  
  $ sudo service dse stop #Stop DataStax Enterprise

- **Cassandra tarball installations:**
  
  $ ps auwx | grep dse
  $ sudo kill pid #Stop DataStax Enterprise

Usage:

- **DataStax Enterprise 5.0 Installer Services and package installations:**
  
  $ sstablesplit [options] <filename> [<filename>]*

- **DataStax Enterprise 5.0 Installer No-Services and tarball installations:**
  
  $ cd install_location/resources/cassandra
  $ bin/sstablesplit [options] <filename> [<filename>]*

- **Cassandra package installations:**
  
  $ sstablesplit [options] <filename> [<filename>]*

- **Cassandra tarball installations:**
  
  $ cd install_location
  $ bin/sstablesplit [options] <filename> [<filename>]*

Example:

$ sstablesplit -s 40 /var/lib/cassandra/data/data/Keyspace1/Standard1/*

<table>

#### sstableupgrade

This tool rewrites the SSTables in the specified table to match the currently installed version of Cassandra.

If restoring with `sstableloader (page 388)`, you must upgrade your snapshots before restoring for any snapshot taken in a major version older than the major version that Cassandra is currently running.

**Usage:**

- **DataStax Enterprise 5.0 Installer Services and package installations:**

```bash
$ sstableupgrade [options] keyspace table [snapshot]
```

- **DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

```bash
$ cd install_location/resources/cassandra
$ bin/sstableupgrade [options] keyspace table [snapshot]
```

- **Cassandra package installations:**

```bash
$ sstableupgrade [options] keyspace table [snapshot]
```

- **Cassandra tarball installations:**

```bash
$ cd install_location
$ bin/sstableupgrade [options] keyspace table [snapshot]
```

The `snapshot` option only upgrades the specified snapshot.

#### Table 114: Options

<table>
<thead>
<tr>
<th>Flag</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-v</td>
<td>--verbose</td>
<td>Verbose output.</td>
</tr>
<tr>
<td>--debug</td>
<td></td>
<td>Display stack traces.</td>
</tr>
<tr>
<td>-h</td>
<td>--help</td>
<td>Display help.</td>
</tr>
</tbody>
</table>

#### sstableutil

The `sstableutil` will list the SSTable files for a provided table.

**Usage:**

- **DataStax Enterprise 5.0 Installer Services and package installations:**
Cassandra tools

$ sstableutil [--cleanup | --debug | --help | --opslog | --type <arg> | --verbose] keyspace | table

- **DataStax Enterprise 5.0 Installer No-Services and tarball installations:**
  
  $ cd install_location/resources/cassandra
  
  $ bin/sstableutil [--cleanup | --debug | --help | --opslog | --type <arg> | --verbose] keyspace | table

- **Cassandra package installations:**

  $ sstableutil [--cleanup | --debug | --help | --opslog | --type <arg> | --verbose] keyspace | table

- **Cassandra tarball installations:**

  $ cd install_location
  
  $ bin/sstableutil [--cleanup | --debug | --help | --opslog | --type <arg> | --verbose] keyspace | table

**Note:** Arguments for --type option are: all, tmp, or final.

1. Choose a table for which to list SSTables files.

   $ sstableutil --all cycling cyclist_name

**sstableverify**

The sstableverify utility will verify the SSTable for a provided table and look for errors or data corruption.

Usage:

- **DataStax Enterprise 5.0 Installer Services and package installations:**

  $ sstableverify [--debug | --extended | --help | --verbose] keyspace | table

- **DataStax Enterprise 5.0 Installer No-Services and tarball installations:**

  $ cd install_location/resources/cassandra
  
  $ bin/sstableverify [--debug | --extended | --help | --verbose] keyspace | table

- **Cassandra package installations:**

  $ sstableverify [--debug | --extended | --help | --verbose] keyspace | table

- **Cassandra tarball installations:**
1. Choose a table to verify.

$ sstableverify --verbose cycling cyclist_name
Troubleshooting

Troubleshooting has moved to Troubleshooting Apache Cassandra (page ).
Apache Cassandra 3.0 release notes

Note: Cassandra is now releasing on a tick-tock schedule.

The latest version of Apache Cassandra 3.0 is 3.0.9.

The CHANGES.txt describes the changes in detail. You can view all version changes by branch or tag in the drop-down list on the changes page.

New features, improvements, and notable changes are described in What’s new in Apache Cassandra 3.0 (page 15).
